นันทิยา ข้อชะรัด : องค์ประกอบทางเคมีของใบยางสาครป่าและใบประยงค์ใบใหญ่และฤทธิ์ทางชีวภาพ (CHEMICAL CONSTITUENTS OF *AGLAIA FORBESII* AND *AGLAIA OLIGOPHYLLA* LEAVES AND THEIR BIOLOGICAL ACTIVITIES) อ. ที่ปรึกษา : รศ. ดร. เอกรินทร์ สายฟ้า, 257 หน้า.

การศึกษาองค์ประกอบทางเคมีของใบยางสาครป่า (วงศ์ Meliaceae) สามารถแยกสารใหม่ในกลุ่ม cyclopenta[bc]-benzopyran flavaglines 3 ชนิด คือ desacetylpyramidaglains A, C และ D และสารใหม่ในกลุ่มของ cycloartane triterpenoid 1 ชนิด คือ (23*R*,24*S*)-23,24,25-trihydroxycycloartan-3-one รวมทั้งพบสารที่เคยมีรายงานมาแล้วอีก 8 ชนิด ได้แก่ สารกลุ่ม bisamide 1 ชนิด คือ pyramidatine, สารกลุ่ม sesquiterpenoid 1 ชนิด คือ spathulenol, สารกลุ่ม pregnane steroids 2 ชนิด คือ 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(Z)-en-16-one และ 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(E)-en-16-one, สารกลุ่ม stigmastane steroids 2 ชนิด คือ สารผสมของ β -sitosterol และ stigmasterol และ สารกลุ่ม triterpenoids ซึ่งพบได้ทั่วไป 2 ชนิด คือ lupeol และ lupenone ส่วนการศึกษาองค์ประกอบทางเคมีของใบประยงค์ใบใหญ่ สามารถแยกสารได้ 11 ชนิด โดยเป็นสารกลุ่ม cyclopenta[*b*]benzofuran flavagline 1 ชนิด คือ rocagliaol, สารกลุ่ม dammarane triterpenoids 8 ชนิด คือ dipterocarpol, สารผสมของ ocotillone และ cabraleone, ocotillol-II, 20*S*,24*S*-dihydroxydammar-25-en-3-one, 20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone และ สารผสมของ 20*S*,25-epoxy-24*R*-hydroxydammar-3 α -ol และ 20*S*,25-epoxy-24*R*-hydroxydammar-3 β -ol และสารกลุ่ม bisamides 2 ชนิด คือ สารผสมของ odorine และ 2'-epi-odorine การพิสูจน์โครงสร้างทางเคมีของสารที่แยกได้นี้ อาศัยการวิเคราะห์สเปกตรัมของ UV, IR, MS และ NMR ร่วมกับการเปรียบเทียบข้อมูลของสารที่ทราบโครงสร้างแล้ว โดยสารแต่ละชนิดที่สกัดได้จากพืชทั้งสองชนิดได้ถูกนำไปทดสอบฤทธิ์ต้านเชื้อวัณโรค (*Mycobacterium tuberculosis* H₃₇Ra), ฤทธิ์ต้านไวรัสเริม HSV-1, และ ฤทธิ์ความเป็นพิษต่อเซลล์มะเร็งปอด (NCI-H187)

สารสกัดจากยางสาครป่าทั้งหมดแสดงฤทธิ์ต้านเชื้อวัณโรคยกเว้น desacetylpyramidaglains A และ C โดยพบว่า desacetylpyramidaglain D และ pyramidatine แสดงฤทธิ์ได้ดีที่สุด และยังพบว่าสารสกัดบางชนิดจากพืชนี้แสดงฤทธิ์ต้านไวรัสเริม HSV-1 โดยสารดังกล่าวประกอบด้วย 23,24,25-trihydroxycycloartan-3-one, desacetylpyramidaglain D, และ 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(E)-en-16-one ในขณะที่พบว่า lupeol นั้นแสดงความเป็นพิษปานกลางต่อเซลล์มะเร็งปอด (NCI-H187) นอกจากนี้ยังพบว่าสารสกัดจากประยงค์ใบใหญ่ 4 ชนิด ได้แก่ สารผสมของ 20*S*,25-epoxy-24*R*-hydroxydammar-3 α -ol และ 20*S*,25-epoxy-24*R*-hydroxydammar-3 β -ol และ สารผสมของ odorine และ 2'-epi-odorine แสดงฤทธิ์ต้านเชื้อวัณโรค

KEY WORD : *AGLAIA FORBESII* / *AGLAIA OLIGOPHYLL* / MELIACEAE / FLAVAGLINES / BISAMIDES /
CYCLOPENTA[bc] BENZOPYRAN

NANTIYA JOYCHARAT : CHEMICAL CONSTITUENTS OF *AGLAIA FORBESII* AND *AGLAIA OLIGOPHYLLA* LEAVES AND THEIR BIOLOGICAL ACTIVITIES. THESIS ADVISOR : ASSOC. PROF. EKARIN SAIFAH, Ph.D., 257 pp.

Investigation of the chemical constituents of the leaves of *Aglaiia forbesii* King. (Meliaceae) led to the isolation of three new cyclopenta[bc]benzopyran type flavaglines, desacetylpyramidaglains A, C and D, and a new cycloartane type triterpenoid, (23*R*,24*S*)-23,24,25-trihydroxycycloartan-3-one, together with the bisamide pyramidatine, the sesquiterpene spathulenol, two pregnane steroids, 2β,3β-dihydroxy-5α-pregn-17(20)-(Z)-en-16-one and 2β,3β-dihydroxy-5α-pregn-17(20)-(E)-en-16-one, two stigmastane steroids, a mixture of β-sitosterol and stigmasterol and two common triterpenoids, lupeol and lupenone. Similar study on the leaves of *A. oligophylla* Miq. yielded eleven of its constituents including the cyclopenta[b]benzofuran flavagline, rocaglaol, eight dammarane type triterpenoids, including dipterocarpol, a mixture of ocotillone and cabraleone, ocotillo-II, 20*S*,24*S*-dihydroxydammar-25-en-3-one, 20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone, and a mixture of 20*S*,25-epoxy-24*R*-hydroxydammar-3α-ol and 20*S*,25-epoxy-24*R*-hydroxydammar-3β-ol, and a mixture of the bisamides odorine and 2'-epi-odorine. The structures of these isolates were determined by extensive spectroscopic studies, including comparison of their UV, IR, MS and NMR properties with previously reported data. Each isolated compounds from the two plants was evaluated for anti-tuberculosis activity against *Mycobacterium tuberculosis* H₃₇Ra, anti-herpes simplex activity, and cytotoxic activity against NCI-H187 small cell lung cancer cell line.

All of the compounds from *Aglaiia forbesii* except desacetylpyramidaglains A and C exhibited anti-TB activity, of which desacetylpyramidaglain D and pyramidatine showed the highest activity. Furthermore, some of the compounds isolated from this plant, including 23,24,25-trihydroxycycloartan-3-one, desacetylpyramidaglain D and 2β,3β-dihydroxy-5α-pregn-17(20)-(E)-en-16-one, also exhibited anti-HSV-1 activity, while lupeol showed moderately cytotoxic activity against NCI-H187 cancer cell line. In addition, four compounds from *Aglaiia oligophylla*, a mixture of 20*S*,25-epoxy-24*R*-hydroxydammar-3α-ol and 20*S*,25-epoxy-24*R*-hydroxydammar-3β-ol, and a mixture of the bisamides odorine and 2'-epi-odorine exhibited anti-TB activity.

ACKNOWLEDGEMENTS

The success of this research would not be realized without the support and assistance of some persons and various institutions to whom I would like to express my deepest gratitude:

Associate Professor Dr. Ekarin Saifah, my thesis advisor, for his excellent advice and untiring supervision during the entire duration of the work.

Prof. Dr. Harald Greger of the Comparative and Ecological Phytochemistry Section, Institute of Botany, University of Vienna, for providing research opportunities and invaluable suggestions during my research in Vienna, Austria.

Prof. Dr. Otmar Hofer of the Institute of Organic Chemistry, University of Vienna, for his kind assistance in NMR measurement and discussion on structure elucidation.

Associate Professor Dr. Rapepol Bavovada of the Department of Pharmaceutical Botany for his useful discussion on structure elucidation.

All the members of my thesis committee for their constructive suggestions and critical review of this thesis.

The Thailand Research Fund (TRF) for financial support (grant no. PHD/0063/2546) through the 2003 Royal Golden Jubilee Ph.D. program.

Nuclear magnetic resonance and infrared spectrometer operators of the Scientific and Technological Research Equipment Center, Chulalongkorn University for providing the spectral data and helpful assistance in spectroscopic experiments.

BIOTEC laboratories, NSTD, Thailand for the evaluation of antituberculosis, antimalarial, antiviral and anticancer activities of the plant extracts and pure compounds.

The students and all staff members of the Department of Pharmaceutical Botany, Faculty of Pharmaceutical Sciences, Chulalongkorn University for their friendship, kind support and encouragement throughout the period of my study.

Finally, the most special thanks are due to the late Mr. Patiparn Treechorvitaya and my family for their love, encouragement and moral support.

CHAPTER I

INTRODUCTION

Aglaiia, the largest genus in the family Meliaceae, is separated from most other genera in the Meliaceae by its characteristic indumentum of stellate hairs or peltate scales. The hairs and scales collectively known as trichomes which are described as scales if they lie flat on the surface of the plant and as hairs if the arms project at various angles outwards from the plant surface. All species of *Aglaiia* are woody, ranging from treelets a few metres high to large trees up to 40 m high. Latex is often present, sometimes flowing rapidly when the trunk is cut. Twigs are stout or slender, apical bud always with dense stellate hairs or peltate scales. Leaves are usually imparipinnate, but occasionally simple or trifoliolate. Leaflets are (1-)3-25, lanceolate, oblanceolate, ovate, obovate, elliptical or oblong, the margin is entire or slightly wavy, one or both surfaces may be rugulose or pitted, in some species almost without indumentum but usually the lower surface has few, numerous or dense hairs or scales like those on the twigs. Inflorescences are usually axillary, occasionally ramiflorous, often several on an apical shoot. Flowers are small (1-10 mm long) and subglobose, ellipsoid or obovoid. They are unisexual, the structure of female flowers is similar to the male but usually slightly larger. Corolla aestivation is imbricate or quincuncial, petals are 3-5, free or united at the base, usually yellow, sometimes pink or white, subrotund, elliptical or obovate, occasionally with stellate hairs or peltate scales on the outside. Stamens are united to form a tube 0.5-8 mm long; anthers are (3-)5-10(-21), usually in a single whorl; anthers in the female flowers are similar but sterile. Ovary is superior, depressed globose or ovoid with dense stellate hairs or peltate scales; style is absent; stigma is ovoid, entire at the apex or with 2,3 or rarely 4 small lobes; ovary and stigma in the male are either poorly developed or similar to the female but sterile. Fruit is subglobose, obovoid or ellipsoids, dehiscence (section *Amoora*) or indehiscence (section *Aglaiia*), covered with stellate hairs or peltate scales (Pannell, 1992).

According to Pannell (1992) and Smitinand (2001), the genus *Aglaiia* consists of over 100 species distributed in the tropical rain forests of Southeast Asia. In Thailand, twenty-eight species can be found as follows; *A. argentea* (Sang khriat klong), *A. aspera*, *A. chittagonga* (Pra song), *A. crassinervia*, *A. cuculata* (Samae daeng), *A. edulis* (Khang khao), *A. elaeagnoidea* (Kraduk - khiat), *A. elliptica*, *A. erythrosperma*, *A. eximia*, *A. exstipulata* (Sang khriat rai hu), *A. forbesii*, *A. grandis*, *A. korthalsii* (Lang sat kao), *A. lawii* (Sang katong), *A. leptantha*, *A. leucophylla*, *A. odorata* (Prayong),

A. odoratissima (Prayong pa), *A. oligophylla* (Pra youg bai yai), *A. pachyphylla*, *A. perviridis*, *A. silvestris* (Chan-chamot), *A. simplicifolia* (Khaduk ling), *A. spectabilis*, *A. tenuicaulis* (Sang khriat bai yai), *A. teymanniana* and *A. tomentosa* (Sang khriat langsat).

Several species of the genus *Aglaia* are traditionally used in folk medicine. In Indo-china, the roots and leaves of *A. odorata* are recommended as pectoral, heart stimulant, febrifuge, tonic, and as a remedy for convulsions; in Malay Peninsula, an infusion of the flowers is administered as a cooling drink for eruptive fevers; in Indonesia, a decoction of the leaves is ingested as a remedy for excessive menses during the menopause (Perry, 1980). In Nepal, the use of *A. roxburghiana* (syn. *A. elaeagnoidea*) to treat a wide range of physical ailments such as asthma, bronchitis, rheumatism, and inflammatory skin diseases has been reported (Kumar and Muller, 1999). Furthermore, the leaves and flowers of *A. duperreana* and *A. odorata* are used in the traditional medicine of several Southeast Asian countries for treatment of asthma and inflammatory skin diseases (Baumann *et al.*, 2002). In China, a decoction of the bark of *A. tsangii* is rubbed on the affected areas (**rubbed** into the hair and scalp) to kill lice. In Indo-China, a decoction of *A. baillonii* is considered to be antifebrile. A decoction of the roots of *A. pleuropteris* is a remedy for jungle fever (malaria). In Thailand, the scented wood of *A. silvestris* (syn. *A. pyramidata*) is used medicinally as antifebrile and antitussive (Perry, 1980). In the Philippines, a decoction of the roots of *A. iloilo* is drunk as an emetic to relieve colic; the bark of *A. elliptica* is boiled and used to treat tumors, while the leaves are applied to wounds (Cui *et al.*, 1997; Perry, 1980).

Previous phytochemical investigations of plants in the genus *Aglaia* have revealed the presence of a variety of compounds with interesting biological activities, including the flavonol-cinnamate derivatives, named flavaglines (cyclopenta[*b*]benzofurans, cyclopenta[*bc*]benzopyrans, and benzo[*b*]oxepines) (Dumontet *et al.*, 1996; Bacher *et al.*, 1999; Proksch *et al.*, 2001), the cinnamic acid-derived bisamides (Brader *et al.*, 1998; Saifah *et al.*, 1988), triterpenoids (dammarane, cycloartane, tirucallane, glabretal, and baccharane types) (Weber *et al.*, 2000; Hwang *et al.*, 2004), steroids (pregnane, cholestane, stigmastane, and ergostane types) (Mohamad *et al.*, 1999; Rivero-Cruz *et al.*, 2004; Su *et al.*, 2006), limonoids (Fuzzati *et al.*, 1996, sesquiterpenes (Roux *et al.*, 1998, lignans (Greger *et al.*, 2000), and flavonoids (Greger *et al.*, 2001). Among these previously known isolates, flavaglines have attracted considerable interest due to their unusual carbon skeleton, and these compounds are confined to the members of the genus *Aglaia*. In addition, some of flavaglines were shown to possess high insecticidal activity, antifungal activity as well as significant cytotoxicity in many different cancer cell lines (Cui *et al.*, 1997; Proksch *et al.*, 2001), while bisamides have been

reported as cytotoxic (Duh *et al.*, 1993) and antiviral (Joshi *et al.*, 1987).

Aglaia forbesii King (Lang Sat Pa) is a large tree of up to 35 metre in height. The leaves (**Figure 1**) are imparipinnate, up to 100 cm long and 60 cm wide, elliptical in outline. The 9-15 leaflets are alternate or subopposite. They all are 8.5-30 cm long and 2-10 cm wide, elliptical or oblong, brown or greenish-brown on lower surface when dry. The inflorescence is up to 35 cm long and 25 cm wide. The peduncle is up to 6 cm in length. The flowers are up to 2 mm long, ovoid, and fragrant. Each flower has 5-6 petals which are obovate, white, yellow or orange-yellow. The fruit is up to 4 cm long and 3.8 cm wide, ellipsoid or subglobose. The grey or greenish-grey pericarp is up to 4 mm thick with white latex, soft, fibrous and flexible. The seed is 1.5-3 cm long, 2-2.2 cm wide, and about 1.5 cm thick, with yellow or pink aril up to 3 mm thick.

The isolation of flavaglines including the cyclopenta[*b*]benzofuran type rocaglaol and ethyrocaaglaol, the cyclopenta[*bc*]benzopyran type aglaforbesins A-B, and the benzo[*b*]oxepine type forbaglins A-B from the CH₂Cl₂ extract of the bark of *Aglaia forbesii*. has been earlier described (Dumontet *et al.*, 1996). However, the chemical constituents and biological activity of the leaves of *Aglaia forbesii* have never been recorded. Preliminary evaluation of the biological activity of *A. forbesii* leaves revealed that the dichloromethane extract exhibited antimycobacterial activity against *Mycobacterium tuberculosis* with MIC values of 25 µg/ml. The extract was also moderately active (35-50%) against herpes simplex virus type 1 (HSV-1) at the non-cytotoxic concentration of 38.1 µg/ml.

Aglaia oligophylla Miq. (Prayong bai yai) is a tree up to 20 (-25) m, with small buttresses. The leaves (**Figure 2**) are imparipinnate, up to 40 cm long and 30 cm wide, obovate in outline. The 3-11 leaflets are opposite or subopposite. They are 4.5-22 cm long, 2-9 cm wide, obovate or elliptical, both surfaces are rather shiny when dry. The inflorescence is up to 10-20 cm long and 9-15 cm wide. The peduncle is up to 4 cm in length. The depressed-globose flower is up to 2 mm long, each of which has 5-6 yellow and obovate petals. The fruit is 1-3 cm in diameter, subglobose. Its pericarp is brown or yellow, either thin, hard and brittle or thick. The seeds are white or brown with sweet edible aril.

Previous phytochemical studies on this plant have revealed the presence of flavaglines including the cyclopenta[*b*]benzofuran type aglaroxins A-B, aglaroxin F, pannellin 1-O-acetate, C-1-oxo, C-2-piriferineaglaroxin A and cyclorocaglamide, and the cyclopenta[*bc*]benzopyran type homothapsakin A and C-8-demethoxy-C7, C8-methylenedioxyaglaforbesin in the CH₂Cl₂ extract of the twigs of *Aglaia oligophylla* Miq. (Dreyer *et al.*, 2001; Bringmann *et al.*, 2003). Preliminary

evaluation for bioactivity activity revealed that the hexane and EtOAc extracts of its leaves exhibited strong cytotoxic activity against NCI-H187 cancer cell line at the IC_{50} values of 3.86 and 4.22 $\mu\text{g/ml}$, respectively, as well as antimalarial activity against *Plasmodium falciparum* (KI stain) at the IC_{50} values of 2.5 and 5.1 $\mu\text{g/ml}$, respectively. In addition, the EtOAc extract also showed antimycobacterial activity against *Mycobacterium tuberculosis* with the MIC value of 100 $\mu\text{g/ml}$.

Therefore, these plants were selected for further investigation of their chemical constituents and biological activity. The purposes of this research are as follows:

1. Isolation and purification of compounds from the leaves of *Aglaia forbesii* and *A. oligophylla*.
2. Determination of chemical structures of the isolated compounds.
3. Evaluation of biological activities of the isolated compounds.

CHAPTER II

HISTORICAL

1. Chemical constituents of *Aglaia* spp.

According to previous phytochemical studies, a number of compounds have been isolated from the genus *Aglaia*. They can be classified as flavaglines (cyclopenta[*b*]benzofurans, cyclopenta[*bc*]benzopyrans, and benzo[*b*]oxepines), bisamides (pyrrolidine and putrescine types), triterpenoids (dammarane, cycloartane, tirucallane, glabretal, and baccharane types), steroids (pregnane, cholestane, stigmastane, and ergostane types), limonoids, sesquiterpenes, lignans, and flavonoids. The distribution of these compounds in *Aglaia* spp. is summarized in **Table 1** and their chemical structures are shown in **Figure 3**.

Table 1. Chemical constituents of plants in the genus *Aglaia*

| Chemical type / Chemical compounds | Sources / Plant part | References |
|---|---|--|
| Flavaglines | | |
| Cyclopenta[<i>b</i>]benzofuran-type | | |
| C-1-O-Acetyl-N-butanoyl-didesmethylocaglamide (1) | <i>A. elliptica</i> (fruits) | Nugroho <i>et al.</i> , 1997b |
| C-1-O-Acetyldemethylocaglamide (2) | <i>A. duperreana</i> (roots, flowers) | Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999 |
| C-1-O-Acetyldidemethylocaglamide (3) | <i>A. duperreana</i> (flowers) | Chaidir <i>et al.</i> , 1999 |
| C-1-O-Acetyl-3'-hydroxydemethylocaglamide (4) | <i>A. duperreana</i> (roots, flowers) | Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999 |
| C-1-O-Acetyl-3'-hydroxymethylocaglate (5) | <i>A. duperreana</i> (roots, flowers) | Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999 |
| C-1-O-Acetyl-3'-hydroxyrocaglamide (6) | <i>A. duperreana</i> (roots, twigs, flowers) <i>A. odorata</i> (twigs) | Nugroho <i>et al.</i> , 1997a; Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999; Nugroho <i>et al.</i> , 1999 |
| C-1-O-Acetylmethylocaglate (7) | <i>A. duperreana</i> (roots, flowers) <i>A. rubiginosa</i> (twigs) | Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999; Rivero-Cruz <i>et al.</i> , 2004 |
| C-1-O-Acetylocaglamide (8) | <i>A. duperreana</i> (roots) | Hiort <i>et al.</i> , 1999 |
| C-1-O-Acetylocaglaol (9) | <i>A. rubiginosa</i> (twigs) | River-Cruz <i>et al.</i> , 2004 |
| N-Butanoyl-didesmethylocaglamide (10) | <i>A. duperreana</i> (flowers) <i>A. elliptica</i> (fruits) <i>A. odorata</i> (flowers) | Nugroho <i>et al.</i> , 1997a; Nugroho <i>et al.</i> , 1997b; Baumann <i>et al.</i> , 2002 |

Table 1. Chemical constituents of plants in the genus *Aglaia* (continued)

| Chemical type / Chemical compounds | Sources / Plant part | References |
|---|---|--|
| Desmethylocaglamide (11) | <i>A. duperreana</i> (flowers, roots, twigs) <i>A. odorata</i> (leaves, flowers, root bark) | Nugroho <i>et al.</i> , 1997a; Chaidir <i>et al.</i> , 1999; Hiort <i>et al.</i> , 1999; Ishibashi <i>et al.</i> , 1993; Engelmeier <i>et al.</i> , 2000; Baumann <i>et al.</i> , 2002 |
| Didesmethylocaglamide (12) | <i>A. argentea</i> (leaves) <i>A. duperreana</i> (flowers, roots) <i>A. elliptica</i> (fruits) <i>A. odorata</i> (flowers) | Dumontet <i>et al.</i> , 1996; Nugroho <i>et al.</i> , 1997a; Hiort <i>et al.</i> , 1999; Nugroho <i>et al.</i> , 1997b Baumann <i>et al.</i> , 2002 |
| C-8b-O-Ethyl-3'-hydroxymethylocaglamide (13) | <i>A. duperreana</i> (flowers) | Chaidir <i>et al.</i> , 1999 |
| C-8b-O-Ethyl-3'-hydroxyrocaglamide (14) | <i>A. duperreana</i> (flowers) | Chaidir <i>et al.</i> , 1999 |
| Ethylocaglaol (15) | <i>A. forbesii</i> (bark) | Dumontet <i>et al.</i> , 1996 |
| C-1-O-Formyloxy-3'-hydroxymethylocaglate (16) | <i>A. dasyclada</i> (leaves) <i>A. spectabilis</i> (bark) | Chaidir <i>et al.</i> , 2001; Schneider <i>et al.</i> , 2000 |
| C-1-O-Formyloxymethylocaglate (17) | <i>A. dasyclada</i> (leaves) <i>A. spectabilis</i> (bark) | Chaidir <i>et al.</i> , 2001; Schneider <i>et al.</i> , 2000 |
| C-3'-Hydroxydemethylocaglamide (18) | <i>A. duperreana</i> (roots) <i>A. odorata</i> (twigs) | Hiort <i>et al.</i> , 1999; Nugroho <i>et al.</i> , 1999 |

2. Biological Activities of plants in the genus *Aglaia*

From various phytochemical reports on plants of the genus *Aglaia*, with only a few exceptions all naturally occurring flavaglines of the cyclopenta[*b*]benzofuran type exhibited strong insecticidal activity, the most active of which are comparable in their activity to the well-known natural insecticide azadirachtin from *Azadirachta indica*. The insecticidal activity of the cyclopenta[*b*]benzofuran flavaglines seems to be largely linked to the integrity of the furan ring system, since two biogenetically closely related compounds of the benzo[*bc*]pyrans and benzo[*b*]oxepines which the oxygen heterocycle of the dihydrobenzofuran nucleus in the cyclopenta[*b*]benzofuran flavaglines is replaced by a bridged pyran and an oxepine ring, respectively, were shown to be inactive. However, the substitution pattern, especially the nature of substituents at C-1, C-2, C-3' and C-8b was also shown to be important for the insecticidal activity. Acylation of the OH group at C-1 (e.g. with formic or acetic acid) always caused a reduction of insecticidal activity. The nature of the amide substituents present at C-2, on the other hand, had little or no influence on the insecticidal activity. Additional oxygen substituents in ring A or B (compared to the substitution pattern of the parent compound rocaglamide) were also shown to have only marginal influences on the insecticidal activity of the respective products. However, a dramatic effect was observed for analogues with replacement of the OH-group at C-8b by a CH₃O or C₂H₅O- substituent, resulting in a total loss of insecticidal activity (Proksch *et al.*, 2001). In addition to insecticidal activity, cytotoxic and antifungal activity of the cyclopenta[*b*]benzofuran flavaglines were also recorded. Furthermore, several studies have shown that the other classes of compounds isolated from the genus *Aglaia*, especially the bisamides, were also exhibited interesting biological activities. Summary of the biological activities of isolated compounds from *Aglaia* plants is shown in **Table 2**.

CHAPTER III

EXPERIMENTAL

1. Sources of Plant Materials

The leaves of *Aglaia forbesii* King. and *Aglaia oligophylla* Miq. were collected from Khao Luang National Park, Nakhon Sri Thammarat Thailand in March, 2004 and compared with authentic specimens of the Herbarium of the Institute of Botany, University of Vienna, Austria (identified by Dr. Caroline Pannell, University of Oxford, England). Voucher specimens of both plants have been deposited at the herbarium of the Department of Pharmaceutical Botany, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand.

2. General Techniques

2.1 Analytical Thin-Layer Chromatography (TLC)

| | | |
|-----------------|---|---|
| Technique | : | One dimension, ascending |
| Adsorbent | : | Silica gel 60 F ₂₅₄ (E. Merck) pre-coated plate |
| Layer thickness | : | 0.2 mm |
| Distance | : | 5.0 cm |
| Temperature | : | Laboratory temperature (30-35 °C) |
| Detection | : | 1) Ultraviolet light (254 and 365 nm) 2) Spraying with anisaldehyde-sulfuric acid solution or 10% sulfuric acid and heating at 100-110 °C for 5 min. |

2.2 Preparative Thin Layer Chromatography (PLC)

| | | |
|-----------------|---|--|
| Technique | : | One dimension, ascending |
| Adsorbent | : | Silica gel 60 F ₂₅₄ (E. Merck) pre-coated plate |
| Layer thickness | : | 1 mm |
| Distance | : | 15 cm |
| Temperature | : | Laboratory temperature (30-35 °C) |
| Detection | : | UV light (254 and 365 nm) |

2.3 Column Chromatography

2.3.1 Liquid Column Chromatography

| | | |
|----------------|---|--|
| Column | : | Flat bottom glass column (various diameter) |
| Adsorbent | : | Silica gel (Merck 60, No. 7734) particle size 0.063-0.200 mm or Silica gel (Merck 60, No. 9385) particle size 0.040-0.063 mm |
| Solvent | : | Various solvent systems depending on materials |
| Packing method | : | Dry and wet packing |
| Sample loading | : | 1) Dry packing: The sample was dissolved in a small amount of suitable organic solvent, mixed with small quantity of adsorbent, triturated, dried and then placed gently on top of the column. 2) Wet packing: The sample was dissolved in a small amount of eluent and then applied gently on top of the column. |
| Detection | : | Fractions were examined by TLC technique in the same manner as described in section 2.1. Fractions with similar chromatographic pattern were combined. |

2.3.2 Gel Filtration Chromatography

| | | |
|----------------|---|--|
| Column size | : | Glass column, 2.2 cm in diameter |
| Gel Filter | : | Sephadex LH-20 (Pharmacia Biotech AB) |
| Solvent | : | CH ₂ Cl ₂ -MeOH (1:1) |
| Packing method | : | Gel filter was suspended in the eluent and left standing to swell for 24 hours prior to use, then poured into the column and allowed to set tightly. |
| Sample loading | : | The sample was dissolved in a small amount of the eluent and then applied gently on top of the column. |
| Detection | : | Fractions were examined by TLC technique in the same manner as described in section 2.3.1 |

2.4 Spectroscopy

2.4.1 Ultraviolet (UV) Absorption Spectra

UV absorption spectra were obtained on a Shimadzu UV-160A spectrophotometer (Pharmaceutical Research Instrument Center, Faculty of Pharmaceutical Sciences, Chulalongkorn University)

2.4.2 Infrared (IR) Absorption Spectra

IR absorption spectra (KBr disc and film) were recorded on a Perkin Elmer FT-IR 1760X spectrometer (Scientific and Technological Research Equipment Center, Chulalongkorn University).

2.4.3 Mass Spectra (MS)

Electrospray Ionization Time of Flight (ESI-TOF) mass spectra were obtained on a Micromass LCT mass spectrometer (National Center for Genetic Engineering and Biotechnology, BIOTEC, Thailand). Electron impact and high-resolution electron impact mass spectra (EIMS and HREIMS) were obtained with a Finnigan MAT 900S apparatus (University of Vienna, Wein, Austria).

2.4.4 Nuclear Magnetic Resonance (NMR) spectra

^1H (300 MHz) and ^{13}C (75 MHz) NMR spectra were obtained on a Bruker DPX-300 FT-NMR spectrometer (Pharmaceutical Research Instrument Center, Faculty of Pharmaceutical Sciences, Chulalongkorn University).

^1H (400 MHz) and ^{13}C (100 MHz) NMR spectra were obtained on a Bruker DRX-400 spectrometer (University of Vienna, Wein, Austria).

^1H (500 MHz) and ^{13}C (125 MHz) NMR spectra were obtained on a JEOL JMN-A 500 spectrometer (Scientific and Technological Research Equipment Center, Chulalongkorn University).

The solvents for NMR spectra were deuterated chloroform (CDCl_3) and deuterated dimethylsulfoxide (DMSO-d_6). The chemical shifts were reported in ppm scale using the chemical shift of the solvent as the reference signal.

2.5 Physical Properties

2.5.1 Melting Points

Melting points were obtained on a Fisher-John melting point apparatus (Department of Pharmaceutical Botany, Faculty of Pharmaceutical Sciences, Chulalongkorn University).

2.5.2 Optical Rotations

Optical rotations were measured on a Perkin-Elmer 241 Polarimeter (University of Vienna, Wein, Austria).

2.6 Solvents

Organic solvents used in the extraction were commercial grade. For column chromatography, solvents were redistilled prior to use.

3. Extraction and Isolation

3.1 Extraction and Isolation of Compounds from the Leaves of *Aglaia forbesii*

3.1.1 Extraction

The dried, powdered leaves (3.5 kg.) of *A. forbesii* were exhaustively extracted with MeOH (3 x 6 L) and filtered. After removing the solvent in *vacuo*, the residue was mixed with Kieselguhr, packed in a column and eluted with n-hexane, CH₂Cl₂, EtOAc and MeOH, successively. Each filtrate was pooled and evaporated to dryness under reduced pressure at temperature not exceeding 40 °C to yield the hexane extract (190 g, 5.42% based on dried weight of leaves), CH₂Cl₂ extract (20 g, 0.57% yield), EtOAc extract (15 g, 0.42% yield) and MeOH extract (17 g, 0.48% yield).

3.1.2 Isolation of Compounds from the Hexane Extract of *A. forbesii* Leaves

The hexane extract (15.0 g) was subjected to column chromatography using silica gel (No. 7734, 400 g) as adsorbent and eluted with 8% EtOAc in hexane to give 100 fractions of approximately 40 ml each and then washed down with MeOH. The fractions were then combined on the basis of their TLC profiles, to give seven fractions: fraction A1 (1.69 g), A2 (1.19 g), A3 (1.33 g), A4 (0.62 g), A5 (2.09 g), A6 (1.86 g) and A7 (5.56 g).

3.1.2.1 Isolation of Compound HAF1

Fraction A2 (1.19 g), which displayed one main orange-brown spot on TLC plate (solvent system: 8% acetone in hexane), was further purified by gel filtration chromatography using a Sephadex LH20 column (100 g, 2.2 x 85 cm) with CH₂Cl₂-MeOH (1:1) as the eluent to yield 10 mg of compound HAF1 as colorless needles.

3.1.2.2 Isolation of Compounds HAF2 and HAF3

Fraction A3 (1.33 g), when developed with 8% acetone in hexane, displayed one major orange-brown spot and another dark violet spot on TLC plate upon detection with 10% sulfuric acid in EtOH. Crystallization of fraction A3 with MeOH yielded 5.6 mg of compound HAF2 as colorless needles while the filtrate, after drying (approximately 1.27 g), was further separated on Sephadex LH20 column (100 g, 2.2 x 85 cm) with CH₂Cl₂-MeOH (1:1) as the

eluent to yield another 9.4 mg of compound HAF2 and 5 mg of compound HAF3 as pale yellow oil.

3.1.2.3 Isolation of Compound HAF4

When developed with 8% acetone in hexane, fraction A4 (0.62 g) displayed one main violet-red spot on TLC plate under detection with 10% sulfuric acid in EtOH. Crystallization of fraction A4 with MeOH yielded 31 mg of compound HAF4 as colorless needles.

3.1.3 Isolation of Compounds from the CH₂Cl₂ Extract of *A. forbesii* Leaves

The CH₂Cl₂ extract (20.0 g) was fractionated by column chromatography using silica gel (No. 7734, 600 g) as adsorbent and eluted with CH₂Cl₂-EtOAc (1:1) to give 88 fractions of approximately 40 ml each and then washed down with MeOH. The fractions with similar chromatographic pattern were then combined to give six fractions: fraction B1 (4.70 g), B2 (2.0 g), B3 (2.0 g), B4 (4.36 g), B5 (1.88 g) and B6 (2.93 g).

3.1.3.1 Isolation of Compound CAF1

Fraction B2 (2 g) was further chromatographed on a silica gel 60 (No. 9385, 60 g) column, eluting with 2% MeOH in CH₂Cl₂, to give sixty fractions of approximately 20 ml each and then washed down with MeOH. The fractions were then combined according to their TLC profile to give five fractions: fraction B21 (64 mg), B22 (58 mg), B23 (457 mg), B24 (226 mg) and B25 (629 mg).

Fraction B23 (457 mg) was purified on Sephadex LH20 column (100 g, 2.2 x 85 cm), eluting with CH₂Cl₂-MeOH (1:1). Twenty-seven fractions, approximately 20 ml each, were collected and then combined according to their TLC behavior into three fractions: fraction B231 (132 mg), B232 (68 mg) and B233 (48 mg). Fraction B232 (68 mg) was further purified on silica gel 60 (No. 9385, 30g) column with 4% MeOH in CH₂Cl₂ as the eluent to give thirty fractions of approximately 10 ml each, then wash down with MeOH. The combined fractions 13-14 from this column yielded 5 mg of the compound CAF1 as white amorphous solid.

3.1.3.2 Isolation of Compounds CAF2 and CAF3

Fraction B233 (48 mg) displayed two spots close together under UV light and appeared as yellow spots on TLC plate (solvent system: hexane-acetone = 72:28) upon detection with 10% sulfuric acid. This fraction was further purified by preparative TLC developed with hexane-acetone (72:28) to give compounds CAF2 (3 mg) and CAF3 (3 mg).

3.1.3.3 Isolation of Compound CAF4

Fraction B3 (2 g) was further chromatographed on a silica gel 60 (No. 9385, 60 g) column, eluting with 40% acetone in hexane to give forty-seven fractions of

approximately 20 ml each and then washed down with MeOH. The fractions with similar TLC profiles were then combined to give four fractions: fraction B31 (694 mg), B32 (112 mg), B33 (468 mg) and B34 (525 mg).

Fraction B32 (112 mg), which displayed one Dragendorff - positive spot on TLC plate, precipitated after partial evaporation of the solvent. The precipitate (52 mg) was further purified by recrystallization in MeOH to yield 12 mg of compound CAF4 as colorless needles.

3.1.3.4 Isolation of Compound CAF5

Fraction B33 (468 mg), was applied to a silica gel 60 (No. 9385, 60 g) column eluted with 6% MeOH in CH_2Cl_2 to yield twenty-two fractions of approximately 10 ml each, then washed down with MeOH. The fractions were then combined on the basis of their TLC profiles to give three fractions: fraction B331 (130.0 mg), B332 (36.8 mg) and B333 (142.5 mg).

Fraction B331 (130 mg), which displayed a Dragendorff - positive spot on TLC plate (R_f 0.5, Hexane- CH_2Cl_2 -EtOAc-MeOH = 10:54:26:10), was further purified by PLC developed with hexane-acetone-methanol (60:34:6) to afford 10 mg of CAF5 as white amorphous powder.

3.1.3.5 Isolation of Compound CAF6

Fraction B333 (142.5 mg) appeared a Dragendorff - positive spot on TLC plate (R_f 0.38, Hexane- CH_2Cl_2 -EtOAc-MeOH = 10:54:26:10). This fraction was further purified on Sephadex LH20 column (100 g, 2.2 x 85 cm), eluting with CH_2Cl_2 -MeOH (1:1), followed by PLC developed with hexane-acetone-methanol (60:34:6) to give 4.8 mg of CAF6 as white amorphous powder.

3.1.3.6 Isolation of Compounds CAF6 and CAF7

Fractions B34 (525 mg) was fractionated on a silica gel 60 (No. 9385, 60 g) column (solvent system: CH_2Cl_2 -EtOAc-MeOH = 80:15:5) to yield fifteen fractions of approximately 20 ml each and then washed down with MeOH. The fractions were then combined according to their TLC profiles to give four fractions: fraction B341 (72 mg), B342 (275 mg), B343 (163 mg) and B344 (49 mg).

Fraction B343 (163 mg), which displayed two Dragendorff - positive spots on TLC plate (R_f 0.42 and 0.38, Hexane- CH_2Cl_2 -EtOAc-MeOH = 10:54:26:10), was further separated by silica gel chromatography, eluting with CH_2Cl_2 -EtOAc-MeOH (80:15:5) to afford fifteen fractions of approximately 15 ml each, then washed down with MeOH. The fractions were combined according to their TLC behavior to afford four main fractions: fraction B343A (5 mg), B343B (20

mg), B343C (17 mg) and B343D (55 mg). Fraction B343C (17 mg) displaying a Dragendorff - positive spot on TLC plate (R_f 0.38, Hexane- CH_2Cl_2 -EtOAc-MeOH = 10:54:26:10) was further purified by PLC (solvent system: CH_2Cl_2 -EtOAc-MeOH = 80:15:5) to yield another 5.2 mg of compound CAF6 while fraction B343B (20 mg), which displayed a Dragendorff - positive spot on TLC plate (R_f 0.42, Hexane- CH_2Cl_2 -EtOAc-MeOH = 10:54:26:10), was further purified in the same manner to yield 6 mg of compound CAF7 as white amorphous powder.

3.2 Extraction and Isolation of Compounds from the Leaves of *A. oligophylla*

3.2.1 Extraction

The dried leaves (1.7 kg) of *A. oligophylla* were ground, macerated with MeOH (3 x 6 L) and filtered. After removing the solvent in *vacuo*, the residue was mixed with Kieselguhr, packed into a column and eluted with n-hexane, EtOAc and MeOH, successively. Each filtrate was pooled and evaporated to dryness under reduced pressure at temperature not exceeding 40 °C to yield the hexane extract (76.86 g, 4.52% based on dried weight of leaves), EtOAc extract (53.14 g, 3.12% yield) and MeOH extract (46.41 g, 2.73% yield).

3.2.2 Isolation of Compounds from the Hexane Extract of *A. oligophylla* leaves

The hexane extract (16.0 g) was separated by column chromatography using silica gel 60 (No. 7734, 500 g) as adsorbent and eluted with 8% acetone in hexane. A total of one-hundred and seventy fractions (30 ml each) were collected and combined according to their TLC behavior into eight fractions: fraction C1 (2.36 g), C2 (1.88 g), C3 (1.62 g), C4 (3.59 g), C5 (3.14 g), C6 (385 mg), C7 (149 mg) and C8 (2.26 g).

3.2.2.1 Isolation of Compounds HAO1 and HAO2

Fraction C2 (1.88 g) was subjected to repeated gel filtration chromatography, using two successive Sephadex LH 20 columns (100 g, 2.2 x 85 cm) eluted with CH_2Cl_2 -MeOH (1:1). The fractions, approximately 10 ml each, were combined according to their TLC profiles to give three main fractions: fraction C21 (22.3 mg), C22 (43.4 mg), and C23 (79.8 mg). Fraction C22 (43.4 mg) was recrystallized in MeOH to yield 17.8 mg of HAO1 as colorless needles. Furthermore, fraction C23 (79.8 mg) was applied to silica gel 60 (No. 9385, 60 g) column, eluting with 6% EtOAc in hexane to give forty-five fractions of approximately 20 ml each, then washed down with MeOH. The fractions were combined according to their TLC patterns into five fractions: C231 (93.6 mg), C232 (52.4 mg), C233 (126 mg), C234 (76.9 mg) and C235 (223.6 mg).

Fraction C232 (52.4 mg) gave another 12.6 mg of compound HAO1 by recrystallization in MeOH, while fraction C234 (76.9 mg), which displayed one main yellow spot on

TLC plate (Hexane-EtOAc = 4:1), was further purified by recrystallization in MeOH to yield 24.7 mg of compound HAO2 as colorless needles.

3.2.2.2 Isolation of Compound HAO3

Fraction C3 (1.62 g) was fractionated on silica gel 60 (No. 9385, 60 g) column eluted with hexane-acetone (76:24) to give forty-five fractions of approximately 20 ml each, then washed down with MeOH. The fractions with similar chromatographic pattern were combined to afford four fractions: C31 (55.6 mg), C32 (565 mg), C33 (38 mg) and C34 (529 mg).

Fraction C32 (565 mg) dissolved in acetone, precipitated after partial evaporation of the solvent. The precipitate was chromatographed on a silica gel column using 16% acetone in hexane as the eluent. A total of forty fractions (fraction size: 20 ml) were collected and combined to give five main fractions: fraction C321 (187.3 mg), C322 (12.2 mg), C323 (26.2 mg), C324 (38.4 mg) and C325 (264.7 mg).

Fraction C322, after recrystallized in MeOH, gave 12.2 mg of a mixture of β -sitosterol and stigmasterol. Fraction C324 (38.4 mg) was further purified by Sephadex LH20 column (100g, 2.2 x 85 cm) eluted with CH_2Cl_2 :MeOH (1:1) to yield 13 mg of compound HAO3 as colorless needles.

3.2.2.3 Isolation of Compound HAO4

Fraction C33 (38 mg) was recrystallized in MeOH to give 5.8 mg of compound HAO4 as colorless needles.

3.2.2.4 Isolation of Compound HAO5

Chromatographic separation of fraction C6 (385.2 mg) using silica gel 60 (No. 9385, 60 g) column eluted with hexane-acetone (72:26) yield forty-two fractions (fraction size: 20 ml). The fractions were then combined according to their TLC profile into four fractions: fraction C61 (43.3 mg), C62 (64.0 mg), C63 (116.0 mg) and C64 (98.5 mg). Fraction C61 (43.3 mg) showed a major dark green spot on TLC plate after being detected with anisaldehyde-sulfuric acid solution. This fraction was further purified by Sephadex LH20 column (100 g, 2.2 x 85 cm) eluted with CH_2Cl_2 -MeOH (1:1) to afford 8 mg of compound HAO5 as white amorphous solid.

3.2.2.5 Isolation of Compound HAO6

When developed with CH_2Cl_2 -EtOAc-Hexane (40:40:20), fraction C63 (116 mg) displayed two spots of similar R_f values under UV light and appeared as yellow spots on TLC plate upon detection with anisaldehyde-sulfuric acid solution. This fraction was subjected to silica gel chromatography, eluting with CH_2Cl_2 -EtOAc-Hexane (60:20:20). The eluates (40 fractions)

were collected 15 ml per fraction and then combined on the basis of their TLC behavior to give three main fractions: fraction C631 (8.3 mg), C632 (77.6 mg) and C633 (24.6 mg). Fraction C632 (77.6 mg) was chromatographed on a silica gel 60 (No. 9385, 50 g) column eluted with CH_2Cl_2 -EtOAc-Hexane (40:40:20) to yield 5 mg of HAO6A (R_f 0.36, CH_2Cl_2 -EtOAc-Hexane = 40:40:20) and 6.2 mg of HAO6B (R_f 0.30, CH_2Cl_2 -EtOAc-Hexane = 40:40:20).

3.2.2.6 Isolation of Compound HAO7

Fraction C7 (149 mg) gave a precipitate after partial evaporation of the solvent. This precipitate was further subjected to column chromatography using a column of Sephadex LH 20 (100 g, 2.2 x 85 cm) eluted with CH_2Cl_2 -MeOH (1:1), followed by recrystallization in MeOH to give 13.3 mg of compound HAO7 as colorless needles.

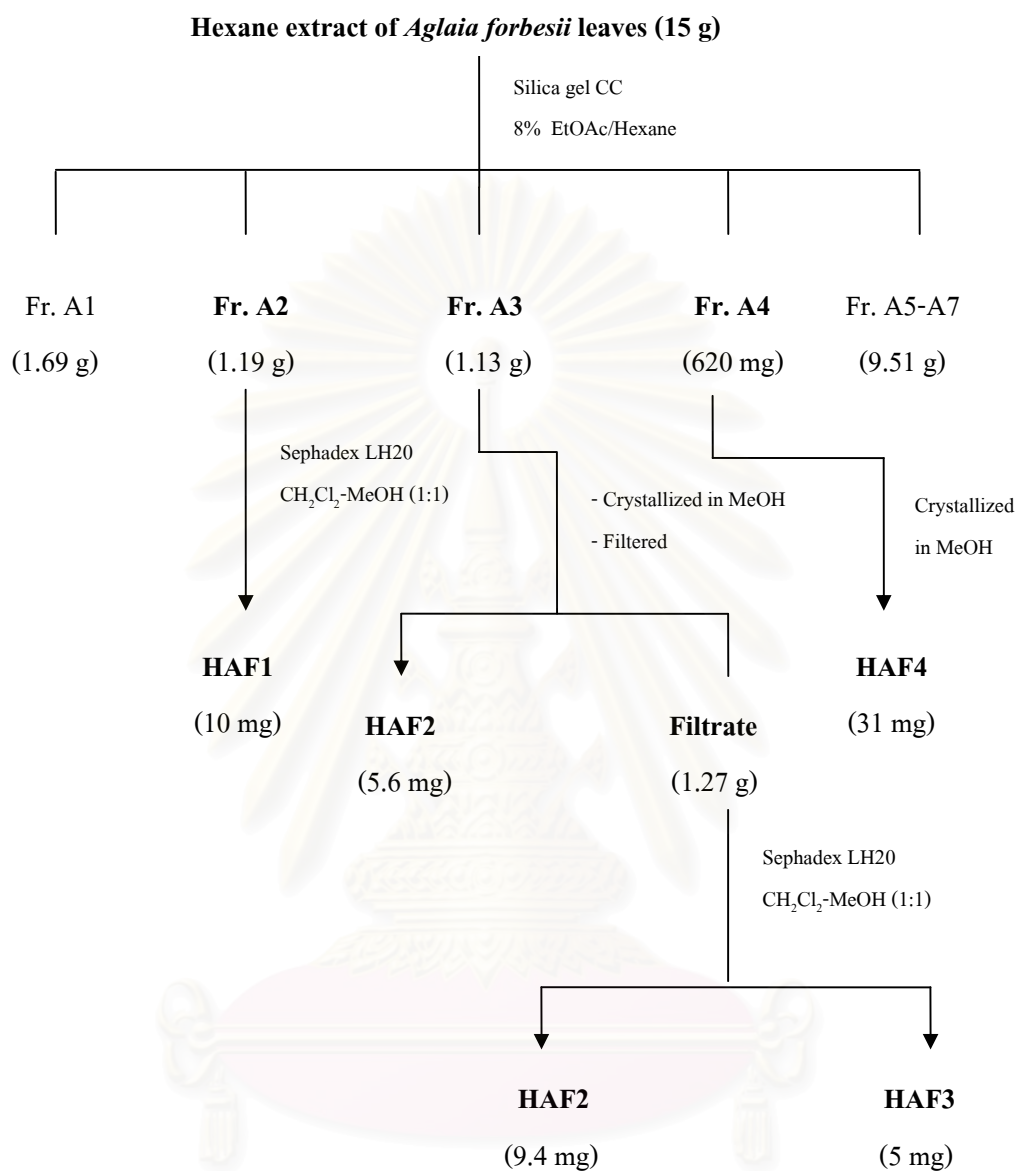

3.2.3 Isolation of Compound from the EtOAc Extract of *A. oligophylla* leaves

The EtOAc extract (20 g) was fractionated by column chromatography using silica gel (No. 7734, 600 g) as adsorbent and eluted with 4% EtOAc in CH_2Cl_2 to give two hundred fractions of approximately 40 ml each and then washed down with MeOH. These fractions were then combined according to their TLC patterns to afford six fractions: fraction D1 (3.70 g), D2 (4.12 g), D3 (2.0 g), D4 (2.36 g), D5 (2.07 g) and D6 (3.97 g).

3.2.3.1 Isolation of Compound EAO1

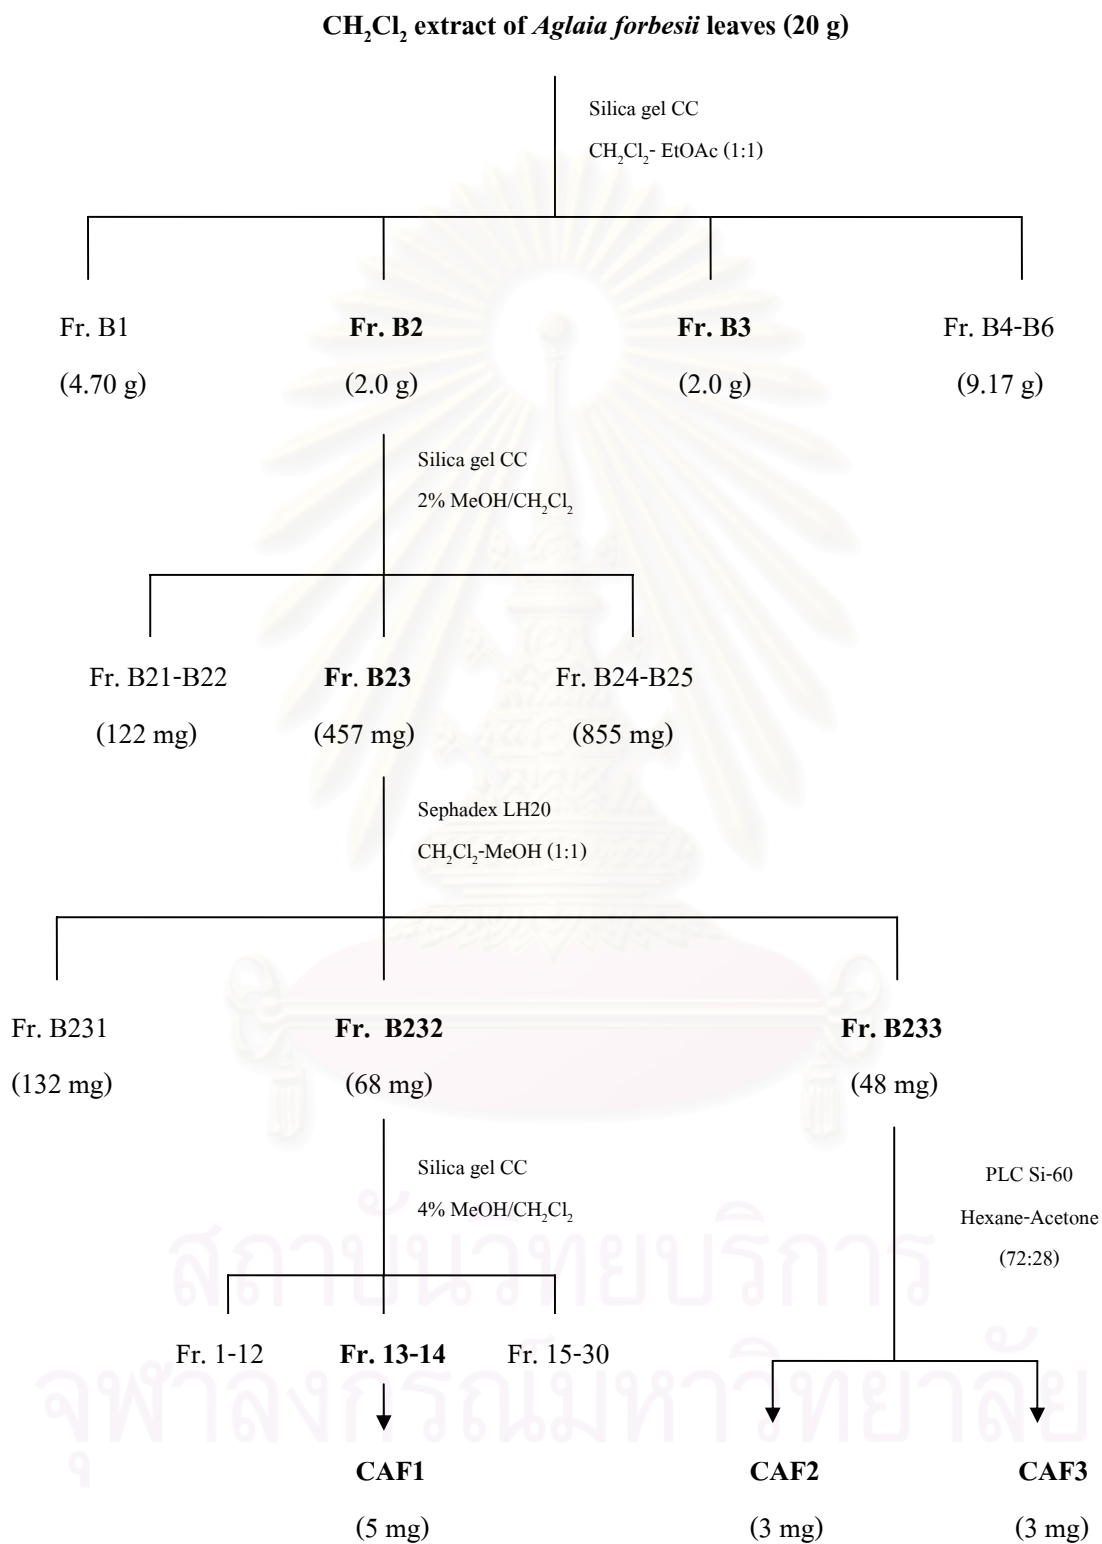

Fraction D3 (2.0 g) gave a precipitate after partial evaporation of the solvent. This fraction was further subjected to column chromatography using silica gel 60 (No. 9385, 150 g) eluted with CH_2Cl_2 -EtOAc- MeOH (60:35:5), followed by Sephadex LH 20 (100 g, 2.2 x 85 cm) eluted with CH_2Cl_2 :MeOH (1:1) to yield, after recrystallization in acetone, 6.8 mg of compound EAO1 as colorless needles.

5. Evaluation of Biological Activities

5.1 Determination of Antimycobacterial Activity

Antimycobacterial activity was assessed against *Mycobacterium tuberculosis* H₃₇Ra using the Microplate Alamar Blue Assay (MABA) (Collins and Franzblau, 1997). The mycobacteria were grown in 100 ml of 7H9GC broth containing 0.005 % Tween 80. Culture was incubated in 500 ml plastic flask on a rotary shaker at 200 rpm and 37 °C until they reached an optical density of 0.4-0.5 at 550 nm. Bacteria were washed and suspended in 20 ml of phosphate-buffered saline and passed through a filter. The filtrates were aliquoted and stored at -80°C. The susceptibility testing was performed in 96-well microplates. Samples were initially diluted with either dimethyl sulfoxide or distilled deionized water, then diluted by Middlebrook 7H9 media containing 0.2 % v/v glycerol and 1.0 g/L 7H9GC broth, and subsequent two-fold dilutions were performed in 0.1 ml of 7H9CG broth in microplates. Frozen inocula were diluted 100 times in 7H9GC broth and adding of 0.1 ml to the well resulted in final bacterial titers of about 5×10^4 CFU/ml. The wells containing sample only were used to determine whether the test samples themselves can reduce the dye. Additional control wells were consisted of bacteria only (B) and medium only (M). Plates were incubated at 37 °C. Starting at day 6 of the incubation, 20 µl of Alamar Blue solution and 12.5 µl of 20 % Tween 80 were added to one B well and one M well, and the plates were reincubated at 37 °C. The B wells were observed for a color change from blue to pink, at which time reagents were added to all remaining wells. Plates were then incubated at 37 °C, and results were recorded at 24 h after the addition of reagents. Visual MIC values were defined as the lowest concentration of sample that prevented a color change. Rifampicin, isoniazid and kanamycin sulfate, which are standard drugs in the treatment of tuberculosis, were used as the reference compounds.

5.2 Determination of Antimalarial Activity

The parasite *Plasmodium falciparum* (K1, multi-drug resistant strain) was cultivated *in vitro* using the method of Trager and Jensen (Trager and Jensen, 1976) in RPMI 1640 medium containing 20 mM HEPES (N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid), 32 mM NaHCO₃ and 10 % heat-inactivated human serum with 3 % erythrocytes and incubated at 37 °C in an incubator with 3 % CO₂. The cultures were diluted with fresh medium and erythrocytes every day according to cell growth. Quantitative assessment of antimalarial activity *in vitro* was determined by microculture radioisotope

techniques based upon the method of Desjardins *et al.* (1979). Briefly, a mixture of 200 μl of 1.5 % erythrocytes with 1 % parasitemia at the early ring stage was pre-exposed to 25 μl of the medium containing a test sample dissolved in 1% DMSO (0.1 % final concentration) for 24 h, employing the incubation condition described above. Subsequently, 25 μl of [^3H]-hypoxanthine (Amersham, USA) in culture medium (0.5 μCi) were added to each well and the plates were incubated for an additional 24 h. Levels of incorporated labeled hypoxanthine indicating parasite growth were determined using the TopCount microplate scintillation counter (Packard, USA). The IC_{50} value represents the concentration which indicates 50 % reduction of parasite growth. The standard sample for positive control was dihydroartemisinin (DHA).

5.3 Determination of Cytotoxic Activity

5.3.1 Human Small Cell Lung Carcinoma (NCI-H187)

Cytotoxicity to NCI-H187 cells (human small cell lung carcinoma, ATCC CRL-5804) was determined by MTT assay (Plumb, Milroy and Kaye, 1989). Briefly, cells were diluted to 10^5 cells/ml. Test compounds were diluted in distilled water and added to microplates in a total volume of 200 μl . Plates were incubated at 37 °C, 5% CO_2 for 5 days. Then, 50 μl of 2 mg/ml MTT solution (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide; thiazolyl blue) was added to each well of the plate. The plates were wrapped with aluminium foil and incubated for 4 h. After the incubation period, the microplates were spun at 200 rpm for 5 min. MTT was then removed from the wells and the formazan crystals were dissolved in 200 μl of DMSO and 25 μl of Sorensen's glycine buffer. Absorbance was read in microplate reader at the wavelength of 510 nm. The reference substance was ellipticine and doxorubicin. The activity was expressed as 50 % inhibitory concentration (IC_{50}). The criteria of cytotoxic potency of the compound testing in this system are as follows:

| IC_{50} ($\mu\text{g/ml}$) | Activity |
|---------------------------------------|-------------------|
| > 20 | Inactive |
| > 10 – 20 | Weakly active |
| 5 – 10 | Moderately active |
| < 5 | Strongly active |

5.3.2 Vero cell

Compounds were tested for their toxicity against Vero cells (African green monkey kidney fibroblast), using colorimetric microplate assay (Skehan *et al.*, 1990). Briefly, cells at a logarithmic growth phase were harvested and diluted to 10^5 cells/ml with fresh medium and gently mixed. Extracts or test compounds were diluted in distilled water and put into microplates in a total volume of 200 μ l. Plates were incubated at 37 °C, 5 % CO₂ for 72 h. After the incubation period, cells were fixed by 50 % trichloroacetic acid. The plates were incubated at 4 °C for 30 min, washed with tap water and air-dried at room temperature. The plates were then stained with 0.05 % sulforhodamine B (SRB), dissolved in 1 % acetic acid for 30 min. After the staining period, SRB was removed with 1 % acetic acid. Plates were air-dried before the bound dye was solubilized with 10 mM Tris-base for 5 min on shaker. Absorbance was read in microplate reader at the wavelength of 510 nm. If % cell viability \geq 50%, IC₅₀ was reported as > 50 μ g/ml and if % cell viability $< 50\%$, IC₅₀ was reported from two-fold serial dilution. Ellipticine and DMSO were used as positive and negative control, respectively.

5.4 Determination of Anti-Herpes Simplex Activity

Anti-herpes simplex virus type 1 (HSV-1) activity of pure compounds was tested against HSV-1 strain ATCC VR 260, using colorimetric microplate assay (Skehan *et al.*, 1990). The growth of host cells (Vero cell line ATCC CCL-81) infected with the virus and treated with the extract was compared with control cells, which were infected with virus only. Acyclovir and DMSO were used as positive and negative control, respectively. The extracts were tested at non-cytotoxic concentrations (inhibition of cell growth < 50 %). The potency of activity criteria are as follows:

| % Inhibition | Potency of Activity |
|---------------------|----------------------------|
| 25-35 % | weak active |
| 35-50 % | moderate active |
| > 50 % | active |

Extracts that inhibited virus more than 50 % were further tested to determine the IC₅₀ values.

CHAPTER IV

RESULTS AND DISCUSSION

Chromatographic separation of the n-hexane fraction of the methanolic leaf extract of *Aglaia forbesii* King. yielded 5 compounds (HAF1, HAF2, HAF3 and HAF4; a mixture of HAF4A and HAF4B, whereas the CH₂Cl₂ fraction afforded 7 compounds (CAF1, CAF5, CAF6, CAF7, CAF2, CAF3 and CAF4).

The methanolic leaf extract of *Aglaia oligophylla* Miq. was mixed with Kieselguhr, packed in a column and eluted with n-hexane, EtOAc and MeOH, successively. Nine compounds (HAO1, HAO2; a mixture of HAO2A and HAO2B, HAO3, HAO4, HAO5, HAO6; a mixture of HAO6A and HAO6B, and HAO7) were isolated from the n-hexane fractions while the EtOAc fraction was chromatographed to yield compound EAO1 (a mixture of EAO1A and EAO1B).

The structure determination of these isolated compounds was based on spectroscopic methods (UV, IR, MS, 1D and 2D NMR), and comparison with those reported in the literature.

1. Structure Determination of Compounds Isolated from *Aglaia forbesii*

1.1 Identification of Compound HAF1

Compound HAF1 was isolated as colorless needle crystals. The molecular formula C₃₀H₄₉O for this compound was deduced from its mass spectrum ([M]⁺ at *m/z* 424) (**Figure 6**) in combination with the ¹H and ¹³C APT spectrum (**Figures 8 and 9**) and its IR spectrum (**Figure 7**) which indicated the presence of carbonyl function (1705 cm⁻¹) and a terminal methylene group (1644 cm⁻¹).

Preliminary comparison of the ¹H and ¹³C NMR spectral data (**Figures 8 and 9**) of this compound with those of HAF2 revealed that their NMR spectra were closely similar, including the presence of seven tertiary methyl groups and one isopropenyl group. However, instead of secondary alcohol as in HAF2, a keto carbonyl could be detected at δ_C 218 in this compound. Two singlet signals at δ_H 4.66/4.54 (each *br s*, H₂-29) in the ¹H NMR spectra indicated that an exomethylene group was still present in this molecule. All these data suggested that the compound has a lupane skeleton system identical to that of HAF1.

The assignment of ketone carbonyl at the C-3 position was deduced from the signal at δ_C 218

in the ^{13}C spectrum together with the deshielded methylene protons in the region δ_{H} 2.34-2.54 in the ^1H NMR spectrum, typical for H_2 -2 vicinal to ketone group in a keto-triterpenoid (Tanaka, Tabuse and Matsunaga, 1988).

According to the above spectral evidence and by comparison of its ^{13}C NMR spectral data (**Table 3**) with the reported data (Carpenter, Sotheeswaran, and Sultanbawa, 1980), compound HAF1 was identified as lupenone.

Lupenone, one of the most common triterpene, has previously been reported to exhibit strong viral plaque inhibitory effect against HSV-1 and HSV-2 (Madureira *et al.*, 2003).

1.2 Identification of Compound HAF2

Compound HAF2 was obtained as colorless needle crystals. The compound gave violet color to Liebermann-Burchard test, indicating the presence of triterpenoid. The IR (**Figure 10**) spectrum showed the presence of hydroxyl group in this molecule (3436 cm^{-1}).

The ^1H NMR (**Figure 11**) spectrum exhibited signals corresponded to the lupane-type triterpenoid (Tanaka, Tabuse and Matsunaga, 1988) which including six tertiary methyl groups (δ_{H} 0.98, 0.77, 0.84, 1.04, 0.96 and 0.80; Me-23-Me-28, respectively), one vinylic methyl (δ_{H} 1.68, Me-30), one terminal methylene (δ_{H} 4.66/4.54, each *br s*, H₂-29), a C-3 α carbinolic methine proton (δ_{H} 3.17, *dd*, $J = 10.8, 5.4$ Hz, H-3) and the remaining signals due to methylene and methine protons in the high field region (δ_{H} 0.90-1.70).

The ^{13}C NMR spectrum (**Figure 12**) together with the DEPT experiment resolved the 30 carbon signals as seven methyl, eleven methylene, six methine and six quaternary carbons, thus also supporting the triterpenoid structure. The presence of isopropenyl group was deduced from the signals of two olefinic carbons and the vinylic methyl carbon resonated at δ_{C} 150.9 (C-20), 109.3 (C-29) and 19.3 (C-30), respectively, in the ^{13}C spectrum and the corresponding signals in ^1H NMR spectrum including the resonances at δ_{H} 4.66/4.54 (each *br s*, H₂-29), and 1.69 (*s*, Me-30).

The assignment of the relative configuration at C-3 was based on the large coupling constant (δ_{H} 3.17, *dd*, $J = 10.8, 5.4$ Hz, H-3) of the axial carbinolic methine proton, indicating the β -equatorial orientation of 3-OH group.

HAF2 was finally identified to be lupeol, a pentacyclic triterpene of the lupane-type, by TLC comparison with authentic sample and comparison of the ^1H and ^{13}C NMR spectral data (**Table 4**) with those already reported (Reynolds, McLean and Poplawski, 1986).

Lupeol have recently been investigated for its various pharmacological and medicinal properties including anti-inflammatory activity (Geetha and Varalakshmi, 2001), cytotoxicity against human hepatocellular carcinoma (Hep-G2), human epidermoid carcinoma (A-431) and human leukemia HL-60 cells (Aratanechemuge *et al.*, 2004; Moriarity *et al.*, 1998), anti-angiogenic activity on *in vitro* tube formation of human umbilical vein endothelial cells (HUVEC) (You *et al.*, 2003), and antimicrobial activity (Ajaiyeoba *et al.*, 2003).

Table 3. Comparison of the NMR spectral data of lupeol and compound HAF2 (CDCl₃, 75 MHz)

| Position | Compound HAF2 | Lupeol* | Position | Compound HAF2 | Lupeol* |

* Reynolds, McLean and Poplawski, 1986 (in CDCl₃, 100 Mz)

1.3 Identification of Compound HAF3

Compound HAF3 was obtained as pale yellow oil. The EI mass spectrum (**Figure 13**) displayed $[M]^+$ ion peak at m/z 220 corresponding to the molecular formula $C_{15}H_{24}O$. The EIMS also gave mass fragment peak at m/z 202 ($[M-H_2O]^+$), suggesting the presence of hydroxyl group in this molecule. This was also confirmed by IR absorption band (**Figure 14**) at 3383 cm^{-1} .

The APT experiment (**Figure 16**) revealed 15 carbons including three tertiary methyl groups, five methylenes, four methines and three quaternary carbons, one of which was the oxygenated methine carbon (δ_C 80.9, C-4). Two quaternary carbons which resonated at δ_C 153.4 (C-10) and 106.2 (C-14) were those of an exomethylene function.

The ^1H NMR spectra (**Figure 15**) also exhibited the signals of three tertiary methyl groups (δ_H 1.04, 1.05 and 1.28, 3H each, *s*), an exomethylene function (δ_H 4.69/4.67, each *br s*, H₂-14) and two most upfield signals of typical methine protons (δ_H 0.5, *dd*, $J = 9.5, 11.3$ Hz, H-6 and δ_H 0.5, *ddd*, $J = 9.5, 11.3, 6.2$ Hz, H-7) of the aromadendrane framework (Vizzotto *et al.*, 2003).

This compound was further proved to be an aromadendrane sesquiterpenoid by the analysis of 2D NMR (^1H - ^1H COSY, HMQC and HMBC) spectra. The assignment of the hydroxyl group at C-4 was achieved by the downfield shift of this position and was further confirmed by the prominent cross peaks from Me-15 (δ_H 1.28, *s*) to C-3 (δ_C 41.7), C-4 (δ_C 80.9) and C-5 (δ_C 54.3) in the HMBC spectrum (**Figure 17**). Furthermore, HMBC correlations (**Figure 17**) from H₂-14 (δ_H 4.67/4.69, each *br s*) to C-1 (δ_C 53.4) and C-9 (δ_C 38.8), clearly indicated that an exomethylene function was placed in the position 10.

Based on analysis of the above spectral data (**Table 5**) and confirmed by comparison of previously published data (Brochini and Roque, 2000), HAF3 was identified as spathulenol.

The aromadendrane sesquiterpene spathulenol has already been isolated from *A. foveolata* and *A. lawii* (Roux *et al.*, 1998). In addition, it was also reported to be the constituent of *Callicarpa japonica* (Verbenaceae), *Esenbeckia conspecta* (Rutaceae), *Nepeta macrosiphon* Boiss. (Lamiaceae) and the softcoral *Simularia kavarattiensis* (Fraga, 2003).

spathulenol

1.4 Identification of Compound HAF4

Compound HAF4 was obtained as colorless needle crystals. TLC comparison of this compound with an authentic sample (Solvent system: Hexane-Acetone = 84:16), suggested HAF4 could be a mixture of β -sitosterol (HAF4A) and stigmasterol (HAF4B). This was further confirmed by the following evidences.

The ^1H NMR spectrum (Figure 19) exhibited the olefinic proton signal at δ_{H} 5.33, typical for position 6 of both β -sitosterol and stigmasterol, while two double doublet signals at δ_{H} 5.01 and 5.12 were assigned to H-22 and H-23 of stigmasterol, respectively. A deshielded signal at δ_{H} 3.54 in the ^1H NMR spectrum corresponded to the carbinolic methine proton of position 3. This was also confirmed by IR absorption (Figure 18) band at 3357 cm^{-1} (hydroxyl group).

The ^{13}C NMR spectrum (Figure 20) showed four olefinic carbons, two of which resonated at δ_{C} 138.3 and 129.3 were due to the signals for C-22 and C-23 of stigmasterol, respectively. The ratio of the mixture was deduced from the integration value between H-6 and H-22 or H-23 to be 1:1.

Further comparison of the ^{13}C NMR spectral data of HAF4 with the data reported in the literature (Jahodar, Grygarova and Budesinsky, 1988; Rubinstein *et al.*, 1976), confirmed that this compound was a mixture of β -sitosterol and stigmasterol.

β -sitosterol, the most common plant sterol, has previously demonstrated to have interesting therapeutic properties such as antihyperglycemic (Invorra *et al.*, 1988), anti-inflammatory, and antipyretic activities (Gupta *et al.*, 1980).

1.5 Structure Elucidation of Compound CAF1

Compound CAF1 was obtained as white amorphous solid. Its IR spectrum (**Figure 22**) indicated the presence of hydroxy group (3419 cm^{-1}) and ketone carbonyl (1706 cm^{-1}). EI mass spectrum (**Figure 21**) of this compound showed a molecular mass of $m/z = 474$ corresponding to the molecular formula $\text{C}_{30}\text{H}_{50}\text{O}_4$.

The ^1H and ^{13}C NMR spectra (**Figures 23** and **24**) were typical for triterpenes of the cycloartane series. The high field pair of doublets at δ_{H} 0.76 (H-19a) and 0.55 (H-19b) with a geminal coupling constant of 4.3 Hz was characteristic for this class of triterpenes (Inada *et al.*, 1995). The typical 3-keto carbonyl resonated in the ^{13}C NMR at δ_{C} 216.6 and the pair H-2ax and H-2eq at δ_{H} 2.71 and 2.30 in the ^1H NMR. Two deshielded signals at δ_{H} 4.13 and 3.18 indicated two secondary alcohol functions. This was supported by the corresponding doublets in the ^{13}C NMR at δ_{C} 75.0 and 69.7. Additionally, a singlet at δ_{C} 74.3 indicated a tertiary alcohol. The molecular formula $\text{C}_{30}\text{H}_{50}\text{O}_4$ (m/z 474) is in agreement with one keto and three alcohol functions. The ^{13}C resonances (see **Table 7**) of the basic tetracyclic system of cycloartanes were almost identical with literature data, e.g. 21*S*,24*R*-dihydroxycycloart-25-en-3-one isolated from *A. rubiginosa* (Weber *et al.*, 2000). The structure and shift assignments of the remaining 23,24,25-triol side chain atoms were straightforward using 2D methods (^1H - ^1H COSY, HSQC, HMBC, NOESY) (**Figures 25-33**). Inspection of the ^1H - ^1H COSY spectrum showed that a methyl-group doublet (δ_{H} 0.94) associated with C-21 formed part of a $\text{CH}_3\text{-CH-CH}_2$ fragment which allowed identification of positions C-21, C-20 and C-22, respectively. Furthermore, H₂-22 coupled to the oxygenated methine proton (δ_{H} 4.13, *dd*, $J = 9.4, 4.8$ Hz, H-23), which show additional coupling to neighbouring oxygenated methine proton (δ_{H} 3.18, *br s*, $J < 0.5$ Hz, H-24) in the COSY spectrum. Analysis of the HMQC spectrum indicated that these two deshielded methines should be placed at C-23 and C-24, respectively. This was also supported by the HMBC spectrum, which showed correlations between H₂-22/C-23, C24, H-23/C-22, C-24, and Me-21/C-17, C-20, C-22. Finally, two geminal methyl groups could be placed on an oxygenated quaternary carbon (C-25) *via* their HMBC correlations to this carbon and to another carbon of position 24. This complete the side chain of compound CAF1.

Contrary to cycloartanes, this triol side chain is rather common in the related tirucallanes. An X-ray analysis of piscidinol A and 24-*epi*-piscidinol A proved 23*R*,24*S* configuration for the former and 23*R*,24*R* for the latter (McChesney *et al.*, 1997). 24-*Epi*-piscidinol A was found also in *A.*

andamanica (Puripattanavong *et al.*, 2000), however, the ^{13}C chemical shifts of the side chain did not agree with our data. The most striking difference in the ^1H NMR was the coupling constant $^3J_{(\text{H-23},\text{H-24})}$ which was 8.1 Hz, compared to almost zero in CAF1. The resonance for H-24 of CAF1 appeared as a slightly broad singlet (δ_{H} 3.18, $J < 0.5$ Hz) and as a consequence H-23 was a double doublet (δ_{H} 4.13, $J = 9.4, 4.8$ Hz). A broad singlet for H-24 was also observed for piscidinol A and B (McChesney *et al.*, 1997; Govindachari *et al.*, 1995) and the ^{13}C resonances of the side chain agreed also quite well. This implied that the configurations of the side chain in CAF1 are 23*R*,24*S* or 24*S*,24*R*. These two possibilities would show the same NMR pattern and, additionally, one should have in mind that the configurations at carbon atoms 13, 14, 17, and 20 are reversed in the tirucallanes and the same may be true for positions 23 and 24. The known absolute configuration 20*R*, common for all cycloartanes, could be used for the correlation of the side chain configurations. Characteristic NOEs prove that 23*R*,24*S* is indeed correct. It is interesting that the absolute configurations of the two alcohol functions were identical in tirucallanes and cycloartanes, whereas all other comparable configurations were opposite in the two series.

The complete structure corresponds to the usual representation in literature. The partial structure shows a different conformation (rotation about the C20-C22 bond) and is based on the X-ray structure of piscidinol A. Note that a change in conformation by rotation about a single bond inverts the up and down positions within the chain attached to this bond, the absolute configurations remain of course unchanged. Only this more natural presentation is compatible with the NOEs and all observed couplings. Large coupling constants were observed for transoid arrangements like $^3J_{(\text{H-22a},\text{H-20})} = 9.6$ Hz and $^3J_{(\text{H-22b},\text{H-23})} = 9.4$ Hz and small values for cisoid relationships like $^3J_{(\text{H-22a},\text{H-23})} = 4.8$ Hz, $^3J_{(\text{H-22a},\text{H-20})} \sim 4.0$ Hz, and $^3J_{(\text{H-23},\text{H-24})} < 0.5$ Hz (transoid means one H up and the other one down, cisoid means both protons on the same side, either both up or both down). The resonances of Me-26 and Me-27 can also be discriminated by means of different NOE effects. Both terminal methyl groups show NOE contacts to both protons H-23 and H-24, however, in the case of H-23 the NOE to H₃-26 is clearly stronger, in the case of H-24 the NOE to H₃-27. This results in a geometry with all three OH groups pointing upwards in the correct stereochemical view of CAF1, an arrangement which is stabilized by hydrogen bonding. Optimized hydrogen bonds are also the reason that the vicinal torsional angle between H-23 and H-24 is widened up to 80 or 90° (therefore $^3J_{(\text{H-23},\text{H-24})} < 0.5$ Hz). This results in a smaller torsional angle of about 30 or 40° between 23-OH and 24-OH, allowing a better formation of a hydrogen bond. Due to the many substituents

and extensive hydrogen bridging of the three OH functions the chain is relatively rigid and a detailed conformational analysis was possible. The derived structure of CAF1 was (23*R*,24*S*)-23,24,25-trihydroxycycloartan-3-one. This compound have not been described yet in the literature.

(23*R*,24*S*)-23,24,25-trihydroxycycloartan-3-one

* Weber *et al.*, 2000 (in CDCl_3 , 100 MHz)

1.6 Identification of Compound CAF2

Compound CAF2 was obtained as white amorphous solid. EI mass spectroscopy (**Figure 34**) showed molecular ion peak at m/z 332, suggesting the molecular formula of $C_{21}H_{32}O_3$. IR spectrum (**Figure 36**) exhibited both hydroxyl and α,β -unsaturated ketone absorption maxima at 3396 cm^{-1} and 1712 cm^{-1} , respectively.

The ^1H NMR spectrum (**Figures 37 and 38**) showed the presence of two tertiary methyls (δ_{H} 1.01, *s*, Me-18 and 1.05, *s*, Me-19) and one deshielded vinylic methyl (δ_{H} 1.84, *d*, $J = 7.5$ Hz, Me-21). In addition, there was one olefinic proton quartet (δ_{H} 6.48, *q*, $J = 7.5$ Hz), suggesting that this olefinic proton was coupled with the vinylic methyl.

The ^{13}C APT spectrum (**Figure 39**) of this compound showed three methyl groups (δ_{C} 17.6, 14.4 and 13.1), two olefinic carbons (δ_{C} 147.9 and 129.9), two oxygenated methine carbons (δ_{C} 72.3 and 70.0) and one ketonic carbony (δ_{C} 206.5).

All these NMR spectral data, together with the detailed analysis of 2D-NMR (^1H - ^1H COSY, HMQC and HMBC) (**Figures 40-45**) allowed the assignment for this compound to be a pregnane steroid. The signals at δ_{H} 3.66 (*ddd*, $J = 11.3, 4.0, 2.8$ Hz, H-3) and 4.03 (*dt*, $J = 4.0, 2.8$ Hz, H-2), were assigned to a pair of adjacent axial and equatorial carbinolic methine protons, and each of which was further coupled with a methylene group.

The ketone group was located at C-16 as assigned by the HMBC correlations (**Figure 43**) from the C-16 carbonyl carbon to both H₂-15 (δ_{H} 2.19/1.98, *m*) and H-20 (6.48, *q*, $J = 7.5$ Hz). Furthermore, placement of double bond at C-17 was established by the prominent cross peaks from Me-21 (1.84, *d*, $J = 7.5$ Hz) to C-13 (δ_{C} 17.6) and C-16 (δ_{C} 206.5), in the HMBC spectrum (**Figures 44 and 45**).

Finally, from a detailed comparison of the NMR spectral data (**Table 8**) of CAF2 with those already reported (Inada *et al.*, 1997a), the structure of this compound was established as 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(*E*)-en-16-one.

2β,3β-dihydroxy-5α-pregn-17(20)-(E)-en-16-one

* Inada *et al.*, 1997a (in CDCl₃, 400 MHz)

1.7 Identification of Compound CAF3

Compound CAF3 was obtained as white amorphous solid. Its molecular formula was determined by ESI-TOF MS (**Figure 46**) as $C_{21}H_{32}O_3$, from its $[M+H]^+$ ion peak at m/z 333 and the IR absorption bands (**Figure 48**) at 3390 and 1716 cm^{-1} were suggestive of the presence of hydroxyl and carbonyl groups in this structure.

The 1H and ^{13}C NMR spectra (**Figures 49** and **50**) were closely identical to those of CAF2 with the presence of two tertiary methyl groups, one vinylic methyl, two oxygenated methines and one ketone function. In the 1H NMR spectrum, however, the chemical shift of the olefinic proton (δ_H 5.67, q , 7.3 Hz) of this compound significantly differed from that of CAF2.

The data above suggested that the two compounds are the *Z/E* isomers of the side chain moiety. The *Z* configuration of this compound was established based on the appearance of the olefinic proton signal at higher field (δ_H 5.67, q , 7.3, H-20) compared with CAF2 due to the orientation away from the ketonic carbonyl (δ_C 194.5).

Finally, from a detailed comparison of the NMR spectral data (**Table 9**) of CAF3 with previously reported data (Inada *et al.*, 1997a), confirmed the structure of this compound as 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(Z)-en-16-one.

The occurrence of similar pregnane steroids to the ones isolated in this study is quite rare in the plant kingdom, and such compounds have only been isolated from three species in the Meliaceae family [*Melia volkensii* (Roger, Zeng and McLaughlin, 1998), *Aglaia grandis* (Inada *et al.*, 1997) and *Aglaia ponapensis* (Angela *et al.*, 2007)]

1.8 Identification of Compound CAF4

Compound CAF4 was obtained as colorless needle crystals. Its molecular formula was determined by ESI-TOFMS (**Figure 51**) as $C_{20}H_{22}N_2O_2$, from its $[M+H]^+$ ion peak at m/z 323. The prominent and broad maxima at 272 nm in the UV spectrum (**Figure 52**) as well as the typical IR absorption bands (**Figure 53**) at $3316-3427\text{ cm}^{-1}$ (NH), $1620-1634\text{ cm}^{-1}$ ($>N-C=O$) and 1533 cm^{-1} (C=C), showed that this compound belongs to the group of bisamides characteristic for *Aglaia* species (Greger *et al.*, 2001). In addition, the proton signals at δ_H 8.13 and 8.48 in the 1H NMR spectrum (**Figure 54**) as well as the signals resonated at δ_C 164.9 and 166.2 in ^{13}C NMR spectrum (**Figures 55** and **56**) further confirmed the presence of two amide functions.

Previous phytochemical investigation of a number of *Aglaia* species (Brader *et al.*, 1998; Greger *et al.*, 2000; Seger *et al.*, 2002) revealed that the cinnamic acid derived bisamides consist of two acid moieties linked with the diamine part (Brader *et al.*, 1998). The occurrence of a pair of doublets at δ_H 7.42 (H-3'') and 6.63 (H-2'') and ten aromatic protons in the region δ_H 7.35-7.84 together with two carbonyl carbons at δ_C 164.9 and 166.2 suggested the two acid moieties in this molecule would be a cinnamic and a benzoic acid. The large coupling constant of 15.8 Hz between the pair of doublets at δ_H 7.42 and 6.63 suggested the *trans* double bond.

The analysis of the 1H and ^{13}C APT spectral data indicated the signals of diamine part as including four methylene protons in the region δ_H 1.43-1.64 and four other deshielded methylene protons as two double doublets at δ_H 3.21 (*dd*, $J=12.5, 6.6\text{ Hz}$, H₂-2') and 3.28 (*dd*, $J=12.5, 6.6\text{ Hz}$, H₂-5')

Further comparison of the 1H and ^{13}C spectral data (**Table 10**) to previous work (Saifah *et al.*, 1993), identified compound CAF4 as pyramidatine.

A putrescine-type amide, pyramidatine, was previously isolated from a number of *Aglaia* species (see **Table 1**). Evaluation of the cytotoxic potential of this compound against eleven human cancer cell lines has been performed by Saifah *et al* (1993).

* Saifah *et al.*, 1993 (in DMSO- d_6 , 300 MHz)

1.9 Structure Elucidation of Compound CAF5

Compound CAF5 was obtained as white amorphous powder. The HRESI-TOFMS (**Figure 57**) showed $[M+Na]^+$ peaks at $m/z = 675.2678$ matching a molecular formula of $C_{38}H_{40}N_2O_8$ and the IR (**Figure 59**) absorptions indicated the presence of hydroxyl at 3479 cm^{-1} and amide functions at 1620 and 1633 cm^{-1} .

The ^{13}C NMR spectrum (**Figure 61**) showed 38 carbons including signals for three methine carbons (δ_{C} 61.6, 61.7 and 78.7 ppm), four methylene carbons (δ_{C} 26.0, 26.5, 39.0 and 39.4 ppm), ten methine carbons of two mono-substituted aromatic rings, four methine carbons of a para-substituted aromatic ring, two methine carbons of a fourfold substituted aromatic ring and the remaining resonances of twelve quaternary carbons, two of which resonated at δ_{C} 167.6 and 173.3 ppm were amide carbons.

The ^1H -NMR (**Figure 60**) spectrum indicated the presence of characteristic benzene ring signals, including ten aromatic proton signals of two mono-substituted rings at δ_{H} 6.98-7.15 (5H) and 7.45-7.78 (5H), four aromatic proton signals at δ_{H} 6.89 (2H, *ps d*) and 7.74 (2H, *ps d*) for a para-substituted ring and meta-coupled proton signals at δ_{H} 5.77 (*d*, $J = 2.3$) and 6.04 (*d*, $J = 2.3$) and resonances for three methoxy groups at δ_{H} 3.08 (*s*, 6-OMe), 3.71 (*s*, 8-OMe) and 3.77 (*s*, 4'-OMe). Furthermore, three methine proton signals at δ_{H} 3.91 (*d*, $J = 8.6$ Hz, H-3), 4.12 (*d*, $J = 8.6$ Hz, H-4) and 4.90 (*d*, $J = 4.8$ Hz, H-10) were typical of a cyclopenta[*bc*]benzopyran skeleton (Proksch *et al.*, 2001).

The remaining amide proton signals at δ_{H} 6.79 (*br t*, $J = 5.5$, NH-12) and 6.31 (*br t*, $J = 5.5$, NH-17) and four methylene proton signals at δ_{H} 2.90/2.98 (each *m*, H₂-13), 1.14 (2H, *m*, H₂-14), 1.20 (2H, *m*, H₂-15) and 3.23 (2H, *m*, H₂-16) showed correlations in the COSY spectrum (**Figures 62 and 63**), suggesting the presence of 1,4-butanebisamide chain. In the HMBC spectrum (**Figure 64**), a cross peak was observed between signals at δ_{H} 7.78 (2H, *ps d*, H-20, 24) and δ_{C} 167.6 (C-18), indicated that one of the mono-substituted benzene rings is connected to this 1,4-butanebisamide chain. Further HMBC (**Figures 65-69**) correlations from H-3 (δ_{H} 3.91, *d*, 8.6 Hz) to C-2 (δ_{C} 86.8), C-4 (δ_{C} 61.6), C-11 (δ_{C} 173.3), C-1'' (δ_{C} 136.7) and from H-4 (δ_{H} 4.12, *d*, 8.6 Hz) to C-3 (δ_{C} 61.7), C-5 (δ_{C} 83.2), C-5a (δ_{C} 106.0), C-11 (δ_{C} 173.3), C-1'' (δ_{C} 136.7), established the connectivity of the benzoyl-1,4-butanebisamide moiety and the second monosubstituted benzene ring to C-4 (δ_{C} 61.6) and C-3 (δ_{C} 61.7), respectively.

All these data corresponded to cyclopenta[*bc*]benzopyran flavagline with a benzoyl-1,4-butaneamine moiety linked to the flavagline skeleton by an amide function. The benzoyl-1,4-

butanebisamide structure was known from the pyramidaglains A and B and the bisamide pyramidatine.

The ^1H and ^{13}C NMR (**Table 11**) data of CAF5 were partially almost identical with those of pyramidaglain A (Puripattanavong *et al.*, 2000). The only difference was the lack of the acetylation of the 10-OH function in CAF5. The relative configurations in the hydroxylated methano bridge and the two substituents at positions 3 and 4 could be derived from the characteristic NOESY (**Figure 70**) correlations from H-3 to H-4, NH-12, H-2'/6' and H-2''/6'', from H-4 to H-3, 10-OH, NH-12 and H-2''/6'', from H-10 to H-2'/6' and from 10-OH to H-4. The most important NOESY correlations was between 10-OH and H-4 because it proved directly the relative configurations at C-3, C-4 and C-10. Since the resonances for 10-OH and H-10 were accidentally very close at room temperature (δ_{H} 4.88 and 4.90), the NOESY spectrum (**Figure 70**) was recorded also at lower temperatures. At 278 K the broad doublet of 10-OH shifted to 5.25 ppm and the cross peak between 10-OH and H-4 allowed a clear decision. The structure of CAF5 corresponded to the acetylated derivative of pyramidaglain A (Puripattanavong *et al.*, 2000) and was therefore designated as desacetylpyramidaglain A.

desacetylpyramidaglain A

1.10 Structure Elucidation of Compound CAF6

Compound CAF6 was obtained as white amorphous powder. The HRESI-TOF (**Figure 71**) mass spectrum exhibited $[M+Na]^+$ ion peak at m/z 675.2678, suggesting the molecular formula $C_{38}H_{40}N_2O_8$. The UV spectrum showed absorption maxima at 208 (**Figure 72**). The IR spectrum (**Figure 73**) exhibited absorption bands for hydroxy and two amide functionalities at 3479, 1620 and 1633 cm^{-1} , respectively.

The 1H -NMR (**Figure 74**) spectrum indicated the presence of characteristic benzene ring signals, including ten aromatic proton signals of two mono-substituted rings at 6.98-7.10 (5H) and 7.42-7.77 (5H), four aromatic proton signals at δ_H 6.86 (2H, *ps d*) and 7.64 (2H, *ps d*) for a para-substituted ring and meta-coupled proton signals at δ_H 6.10 (*d*, $J = 2.3$) and 6.12 (*d*, $J = 2.3$), resonances for three methoxy groups at δ_H 3.86 (*s*, 6-OMe), 3.77 (*s*, 8-OMe) and 3.79 (*s*, 4'-OMe), three methine proton signals at δ_H 4.67 (*d*, $J = 6.0$ Hz, H-3), 3.44 (*d*, $J = 6.0$ Hz, H-4) and 4.28 (*d*, $J = 9.5$ Hz, H-10), two amide proton signals at δ_H 6.49 (*br t*, $J = 5.5$, NH-12) and 6.52 (*br t*, $J = 5.5$, NH-17) and four methylene proton signals at δ_H 3.31/3.48 (each *m*, H₂-13) and 1.60-3.50 (H₂-14- H₂-16).

The ^{13}C NMR spectrum (**Figure 75**) showed 38 carbons including signals for three methine carbons at δ_C 55.9 (C-3), 65.6 (C-4) and 82.6 (C-10), four methylene carbons at δ_C 39.3 (C-13), 26.3 (C-14), 26.9 (C-15) and 39.7 (C-16), two amide carbons at δ_C 173.8 (C-11) and 1167.7 (C-18), ten methine carbons of two mono-substituted aromatic rings, four methine carbons of a para-substituted aromatic ring, two methine carbons of a fourfold substituted aromatic ring and the remaining resonances of ten quaternary carbons (see **Table 12**).

The 1H and ^{13}C NMR (**Figures 74-75** and **Table 12**) data of compounds CAF5 and CAF6 were comparable, suggesting that compound CAF6 also possesses the same carbon skeleton of cyclopenta[*bc*]benzopyran bearing benzoyl-1,4-butanebisamide moiety in the side chain bisamide.

The analysis of 2D-NMR (1H - 1H COSY, HMQC and HMBC) (**Figures 76-84**) was further confirmed this compound to be a stereoisomer of CAF5. In the HMBC spectrum, the same correlations were also observed for both compounds (see **Table 12**), indicating in CAF6 the same connectivity of the diamide moiety and unsubstituted phenyl ring, as determined for CAF5. This compound was characterised by H-3 β , H-4 α , and 10-OH pointing towards positions 3 and 4. In the NOESY (**Figure 85**) spectrum, crosspeaks from H-3 to H-4, 10-OH, H-2'/6' and H-2''/6''; from H-4 to H-3, NH-12 and H-2''/6''; from

H-10 to 10-OH and 2'/6'; and from 10-OH to H-3 and 5-OH were typical of the cyclopenta[*b*]benzofuran system. The stereochemistry followed immediately from the most informative NOESY correlation between H-3 and 10-OH. The compound was designated as desacetylpyramidaglain D.

According to previous studies on other cyclopenta[*bc*]benzopyran-type flavaglines, the configuration at positions 3 and 4 could be also determined from the analysis of 3J coupling constants of these positions. The $^3J_{(H-3, H-4)}$ of 5-6 Hz is compatible with the H-3 β , H-4 α configuration, while the vicinal coupling constant of 9-10 Hz is compatible with the H-3 α , H-4 β configuration (Proksch *et al.*, 2001; Kim *et al.*, 2006). In accordance with previous finding, the vicinal coupling constant values between H-3 and H-4 were 6.0 and 8.6 Hz, indicating H-3 β , H-4 α and H-3 α , H-4 β in compounds CAF6 and CAF5, respectively.

1.11 Structure Elucidation of Compound CAF7

Compound CAF7 was obtained as white amorphous powder. The molecular formula of $C_{38}H_{40}N_2O_8$ was established by $[M+Na]^+$ peaks at $m/z = 675.2684$ in the HRESI-TOFMS (Figure 86). The IR (Figure 87) absorption bands at 3479 cm^{-1} , 1620 and 1633 cm^{-1} indicated the presence of hydroxyl and two amide functions in this molecule, respectively.

Based on the comparison of the ^1H and ^{13}C NMR (Figures 88-89 and Table 13) data of CAF7 with those of CAF5 together with the analysis of 2D-NMR (^1H - ^1H COSY, HMQC and HMBC) (Figures 90-97) data indicated that CAF7 was also possessed the benzoyl-1,4-butaneamine moiety linked to the flavagline skeleton by an amide function. NOESY (Figure 98) correlations from H-3 to H-4, NH-12, H-2'/6' and H-2''/6''; and from H-4 to H-3, H-10 and H-2''/6'', and the $^3J_{(H-3, H-4)}$ coupling constant (8.9 Hz) revealed that CAF7 was also have the same relative configuration at positions 3 and 4 as determined for compound CAF5. However, the lack of any NOE interactions between H-4 and H-10 in CAF7 suggested this compound is the C-10 epimer of CAF5. The most important cross peak for the position of the methano bridge 10-OH relative to the substituents at C-3 and C-4 was the strong cross peak between H-4 and H-10. The chemical shift of the OH group was at remarkable high field which was probably due to the ring current effect of the close aromatic ring 5a-9a. A model showed that the proton of the 10-OH group was situated above this ring. The compound was named desacetylpyramidaglain C.

2. Structure Determination of Compounds Isolated from *Aglaia oligophylla*

2.1 Identification of Compound HAO1

Compound HAO1 was obtained as colorless needle crystals. EI mass spectrum (**Figure 99**) indicated the $[M]^+$ of this compound as m/z 442 which corresponded to the molecular formula $C_{30}H_{50}O_2$ and indicated an index of hydrogen deficiency of 6. The presence of ketonic carbonyl group and hydroxyl function were inferred from the IR absorption bands at 1704 and 3480 cm^{-1} , respectively (**Figure 100**).

The ^1H spectrum (**Figure 101**) exhibited eight tertiary singlet methyl groups at δ_{H} 0.94 (Me-18), 1.00 (Me-19), 1.15 (Me-21), 1.69 (Me-26), 1.62 (Me-27), 1.08 (Me-28), 1.03 (Me-29) and 0.88 (Me-30), an olefinic proton at δ_{H} 5.12 (t , $J = 7.1$ Hz, H-24), and the deshielded methylene protons at δ_{H} 2.42 (ddd , $J = 13.6, 9.6, 7.6$ Hz, H-2ax) and 2.51 (ddd , $J = 13.6, 7.8, 4.5$ Hz, H-2eq) typical for position 2 in 3-oxo triterpenoid.

The ^{13}C APT experiment (**Figure 102**) displayed 30 carbon signals, corresponding to eight tertiary C-Me groups, ten methylenes, four methines, five quaternary carbons, two sp^2 carbons at δ_{C} 124.6 (C-24) and 131.6 (C-25), and one carbonyl function at δ_{C} 218.8 (C-3).

These data suggested that this compound would be 3-oxodammarane-type triterpene. This hypothesis was supported by the following evidences. HMBC correlations (**Figure 103**) from both signals at Me-28 (δ_{H} 1.08) and Me-29 (δ_{H} 1.03) to δ_{C} 218.8 (C-3) indicated that ketonic carbonyl group was placed in position 3. Placement of hydroxyl group at C-20 (δ_{C} 75.3), judging from the downfield shift of this position, was further confirmed by the HMBC (**Figure 103**) correlation between the signal of Me-21 (δ_{H} 1.15, s) and this deshielded quaternary carbon of position 20. An olefinic proton resonated at δ_{H} 5.12 (t , $J = 7.1$ Hz) showed HMBC (**Figure 103**) cross peaks to sp^2 quaternary carbon at δ_{C} 131.6 (C-25) and both Me-26 (δ_{C} 25.7) and Me-27 (δ_{C} 17.7), clearly indicating the location of this olefinic proton as position 24.

HAO1 was identified as dipterocarpol based on the above spectral evidence and by comparison of the ^{13}C NMR (**Table 14**) with reported data (Tori *et al.*, 1988).

Dipterocarpol was previously reported to be a constituent of various *Dipterocarpus* species (Cascon and Brown, 1972). Although there are also a number of dammarane triterpenes in the genus *Aglaia* (see **Table 1**), to our knowledge, this is the first report on the occurrence of dipterocarpol in the genus *Aglaia*.

2.2 Identification of Compound HAO2

Compound HAO2 was obtained as colorless needle crystals. The EI mass spectrum (**Figure 104**) displayed $[M]^+$ peak at m/z 458, corresponding to the molecular formula $C_{30}H_{50}O_3$. The IR spectrum (**Figure 105**) showed the strong carbonyl absorption at 1705 cm^{-1} , suggesting this structure belongs to the group of keto-triterpenoids.

Both ^1H and ^{13}C NMR spectra (**Figures 106** and **107**) showed double signals, indicating this compound as in a mixture state. Analysis of signal integration for the ^1H NMR spectrum of HAO2 indicated 4:1 ratio of the two components of this mixture.

Based on the ^{13}C APT and HSQC spectra (**Figures 108** and **109**), it was concluded that each triterpenoid possessed eight tertiary methyl groups, ten methylenes, five methines, six quaternary carbons and one carbonyl group. Two of six quaternary carbons (for the major component: δ_{C} 86.3, C-20 and 71.4, C-25; for the minor component: δ_{C} 86.5, C-20 and 70.2, C-25) and one of five methines (for the major component: δ_{C} 83.3, C-24; for the minor component: δ_{C} 86.4, C-24) were carrying oxygen function, judging from the downfield shift of these carbon signals.

The ^{13}C NMR spectrum (**Table 15**) of the major component, however, differed significantly from the minor one only in the chemical shifts of the side chain moiety, suggesting that they are C-24-epimers (epimers are indicated by the suffices **A** and **B**). The signals at δ_{C} 86.3 (C-20) and 83.3 (C-24) of the major component (HAO2A) and δ_{C} 86.5 (C-20) and 86.4 (C-24) of the minor component (HAO2B) were observed to be typical of C-20 and C-24 in the 20,24-epoxy-25-dammaranes reported earlier (Aalbersberge and singe, 1991). The mass spectrum also exhibited the fragment ion characteristic of 20,24-epoxy function at m/z 143 ($C_8H_{15}O_2$).

The ^1H NMR spectrum (**Figure 106**) from the major component (HAO2A) of this mixture exhibited the signals of eight tertiary methyl groups (δ_{H} 0.88, 0.93, 0.99, 1.03, 1.07, 1.12, 1.13 and 1.21; Me-18, Me-30, Me-19, Me-29, Me-28, Me-27, Me-21 and Me-26, respectively) and of oxymethine proton at δ_{H} 3.73 (t , $J = 7.3$ Hz), typical for the H-24R in 20,24-epoxy chain at C-17 as described by Roux *et al* (1998). HSQC (**Figure 110**) correlation between the signal at δ_{H} 3.73 (t , $J = 7.3$ Hz, H-24) and the signal at δ_{C} 83.3 (C-24) was also supported the location of this oxymethine proton at position 24.

The HMBC (**Figures 111** and **112**) correlations from Me-21 (δ_{H} 1.13) to C-17 (δ_{C} 49.5) and C-20 (δ_{C} 86.3) and from H-24 (3.73, t , $J = 7.3$ Hz) to C-20 (δ_{C} 86.3), C-25 (δ_{C} 71.4), C-26 (δ_{C} 24.2) and

C-27 (δ_c 27.4), further confirmed the presence of 20,24-epoxy function in the side chain. The assignment of ketonic carbonyl at C-3 was supported by the HMBC (**Figure 111**) correlations from H₂-2 (δ_H 2.44/2.48, *m*), H₃-28 (δ_H 1.03, *s*) and H₃-29 (δ_H 1.07, *s*) to this ketonic carbonyl (δ_c 218.5, C-3)

The ¹H NMR spectrum (**Figure 106**) from the minor component (HAO2B) also exhibited the signals of eight tertiary methyl groups (δ_H 0.88, 0.94, 1.01, 1.03, 1.07, 1.15, 1.11 and 1.19; Me-30, Me-18, Me-19, Me-29, Me-28, Me-26, Me-21 and Me-27, respectively), however, instead of signal typical for H-24*R* isomer (δ_H 3.73, *t*, *J* = 7.3 Hz) in HAO2A, showed an oxymethine proton at δ_H 3.64 (*dd*, *J* = 7.6 Hz, H-24), typical for the H-24*S* isomer in HAO2B (Roux *et al.*, 1998).

The compound was finally identified by comparison of the ¹³C NMR (**Table 15**) spectral data with the reported values (Aalbersberg and Singh, 1991) as a mixture of ocotillone (HAO2A) and cabraleone (HAO2B).

The co-occurrence of ocotillone and cabraleone in the same plant has previously been reported from several species of Meliaceae such as *Cabralea eichleriana* (Rao *et al.*, 1975), *Dysoxylum richii* (Aalbersberg and Singh, 1991) and *Amoora yunnanensis* (Luo *et al.*, 2000). Ocotillone was responsible for cytotoxic activity of an ethanolic extract of *Dysoxylum cauliflorum* Hiern against KB cells, previously reported by Benosman *et al* (1995).

2.3 Identification of Compound HAO3

Compound HAO3 was obtained as colorless needle crystals. The molecular formula, $C_{30}H_{52}O_3$, was determined for this compound, even though its EI mass spectrum (**Figure 113**) lack the $[M]^+$ peak and showed peak due to $[M-Me]^+$ at 445. The IR spectrum (**Figure 114**) showed the absorption of hydroxyl group at 3399 cm^{-1} .

Comparison of the ^{13}C (**Figure 116**) spectral data of HAO3 with those of HAO2 and the appearance of the characteristic base peak at m/z 143 in the mass spectrum suggested that the two compounds are based on the same carbon skeleton. However, the carbonyl was missing in this compound and an additional signal at δ_{C} 78.9 of oxymethine carbon was observed.

The ^1H NMR (**Figure 115**) spectrum showed the presence of eight tertiary methyl groups (δ_{H} 0.95, 0.83, 1.11, 1.12, 1.20, 0.97, 0.76 and 0.86). Two oxymethine protons could be located at positions 3 (δ_{C} 78.9, δ_{H} 3.19, *dd*, $J = 11.4, 5.0$ Hz) and 24 (δ_{C} 83.3, δ_{H} 3.72, *t*, $J = 7.3$ Hz), judging from the downfield shifts of the signals of these positions. In the HMBC (**Figure 117**) spectrum, prominent cross peaks from H_2 -1 (1.68/0.94, *m*) and both Me-28 and Me-29 to δ_{C} 78.9 (C-3) and from H_2 -22 (1.62/1.17, *m*), H_2 -23 (1.86/1.78, *m*) and both Me-26 and Me-27 to δ_{C} 83.3 (C-24) further confirmed these assignments.

The assignment of the relative configuration of C-24 was based on a NOESY (**Figure 118**) correlation between Me-21 and H-24, suggesting that isopropanol group at C-24 is *trans* to the methyl group at C-20.

Further comparison of the ^1H and ^{13}C (**Table 16**) spectral data of this compound with those already reported (Tanaka, Masuda, and Matsunaga, 1993) confirmed the structure of HAO3 as ocotillol-II.

Ocotillol-II has previously been isolated from the stem of *Aglaia elliptica* and was shown to be devoid of cytotoxic activity against human cancer cell lines (Cui *et al.*, 1997). It was also found as a constituent of *Fouquieria splendens* (Warnhoff and Halls, 1965), *Phyllanthus flexuosus* (Tanaka, Masuda, and Matsunaga, 1993) and *Camellia japonica* (Akihisa *et al.*, 2004).

2.4 Identification of Compound HAO4

Compound HAO4 was obtained as colorless needle crystals. In the mass spectrum (**Figure 119**) the highest detectable peak is at m/z 440, evidently resulting from the loss of 18 units (H_2O) from m/z 458, the presumed molecular ion ($C_{30}H_{50}O_3$). The IR spectrum (**Figure 120**) displayed absorption bands for hydroxyl (3388 cm^{-1}) and carbonyl functionalities (1705 cm^{-1}).

The 1H -NMR spectrum (**Figure 121**) showed signals for six tertiary methyl groups (δ_H 0.88, 0.93, 0.99, 1.03, 1.08, and 1.15) and one allylic methyl (δ_H 1.75). Evidence for the existence of an exomethylene function was provided by the presence of two broad singlets at δ_H 4.95/4.84 (H_2 -26). In addition, signals representing the methylene protons at C-2 and an oxymethine proton at C-24 were located at δ_H 2.50/2.43 (each m , H_2 -2) and 4.04 (m , H-24), respectively. HSQC spectrum (**Figure 123**) showed that the former methylene protons were correlated with a carbon peak at δ_C 34.1(C-2), while the latter exhibited cross peak with the carbon signal at δ_C 76.4 (C-24).

The ^{13}C -MNR (**Figure 122**) data of HAO4 also exhibited signals due to seven tertiary methyl groups (δ_C 16.0, 15.2, 25.5, 17.7, 26.6, 20.9 and 16.3) two olefinic carbons (δ_C 147.6 and 110.9), an oxygenated methine carbon (δ_C 76.4), an oxygenated quaternary carbon (δ_C 75.5), and one ketonic carbonyl (δ_C 218.1).

The 1H and ^{13}C NMR (**Figures 121 and 122**) spectral data showed to be very similar to those of HAO1 and the observed differences in HAO4 of an isopropenyl moiety (δ_C 147.6, C-25; 110.9, C-26; and 17.7, C-27) in the side chain instead of a terminal isopropylidene moiety in HAO1.

All the signals of HAO4 and their connectivity were established by HMBC, HMQC and 1H - 1H COSY experiments. The assignment of two hydroxyls at positions 20 (δ_C 75.1) and 24 (δ_C 76.4) was deduced from the downfield shift of these carbon atoms. The HMBC (**Figure 124**) correlations between Me-21 (δ_H 1.15) and C-20 and between Me-27 (δ_H 1.66) and C-24 further confirmed these assignment. Placement of an exomethylene function at C-25 was established by the correlations between δ_H 4.95/4.84 (H_2 -26) and C-24 (δ_C 76.4) and between δ_H 1.75(Me-27) and δ_C 147.6 (C-25) and δ_C 110.9 (C-26) in the HMBC spectrum (**Figures 125 and 126**).

Based on these spectral data and comparison with earlier report (Mazinovskaya *et al.*, 1992), compound HAO4 was identified as 20(*S*),24(*S*)-dihydroxydammar-25-en-3-one, previously isolated from *Aglaia rubiginosa* (Weber *et al.*, 2000).

* Mazinovskaya *et al.*, 1992 (CDCl₃, 300 MHz)

2.5 Identification of Compound HAO5

Compound HAO5 was obtained as white amorphous solid. Its molecular formula, $C_{26}H_{26}O_6$ was determined from the $[M+H]^+$ peak at m/z 434 (**Figure 127**). The IR (**Figure 129**) absorptions suggested the presence of hydroxyl (3500 cm^{-1}) and aromatic ($3061, 1610, 1454\text{ cm}^{-1}$) in the molecule.

The ^1H NMR spectrum (**Figure 130**) of this compound exhibited signals for three aromatic rings, including two *meta*-coupled aromatic protons at δ_{H} 6.31 (*d*, $J = 1.9$ Hz, H-5) and 6.17 (*d*, $J = 1.9$ Hz, H-7), a characteristic AA'BB' system (δ_{H} 7.02-7.20, *m*, 2H, H-2'/6' and 6.68, *d*, $J = 8.9$ Hz, 2H, H-3'/5') of a *p*-disubstituted benzene ring and a monosubstituted benzene ring (δ_{H} 7.05-7.20, *m*, 3H, H-3''/5'' and H-4'', and 7.01, *dd*, $J = 6.7, 1.3$ Hz, 2H, H-2''/6''). The ^1H NMR spectrum further exhibited signals for methylene protons as a pair of geminally coupled multiplets at δ_{H} 2.75 (*ddd*, $J = 13.9, 13.9, 6.4$ Hz, H-2 α) and 2.20 (*ddd*, $J = 13.7, 6.5, 1.2$ Hz, H-2 β), both of which showed vicinal couplings with the signals of methines at δ_{H} 4.81 (*d*, $J = 5.5$ Hz, H-1) and 4.01 (*dd*, $J = 14.2, 6.5$ Hz, H-3). Thus, the methylene signals at δ_{H} 2.20 and 2.75 should be connected between the methines.

Consistent with this ^1H NMR spectral data analysis, the ^{13}C NMR (**Figure 131**) and HSQC (**Figure 132**) spectra of HAO5 also displayed the signals for tetrasubstituted, a disubstituted and a monosubstituted benzene ring, one oxymethine carbon (δ_{C} 79.1, C-1), and two carbons at δ_{C} 36.4 (C-2) and 53.2 (C-3) of methylene and methine, respectively, and two characteristic deshielded quaternary carbons at δ_{C} 103.5 and 94.8 of C-3a and C-8b of the cyclopenta[*b*]benzofuran skeleton (Rivero-Cruz *et al.*, 2004).

The relative configuration of HAO5 was established primarily by analysis of the splitting patterns and the coupling constants (see **Table 18**) between H-1, H-2 α , H-2 β , and H-3 ($J_{1,2}$ *ca.* 5-7 Hz and $J_{2,3}$ *ca.* 13-14 Hz) indicated a 1 α , 3 β configuration, as well as a *cis*-B/C ring junction (Proksch *et al.*, 2001). These relative configurations were confirmed by 2D NOESY (**Figure 133**) experiments, wherein correlations were observed between H-2'/6' and both H-1 α and H-2 α but not between H-2'/6' and H-3 β .

On the basis of the above evidence and comparison with those already reported (Su *et al.*, 2006), the structure of compound HAO5 was characterized as rocaglaol.

The cyclopenta[*b*]benzofuran flavagline, rocaglaol, which also exists in other species of *Aglaia* (see **Table 1**), show interesting pharmacological properties including cytotoxic (Su *et al.*, 2006) and insecticidal activity (Schneider *et al.*, 2000).

2.6 Identification of Compound HAO6

Compound HAO6 was obtained as colorless needle crystals. It has the molecular formula of $C_{18}H_{24}N_2O_2$ as determined by $[M+Na]^+$ peak at $m/z = 323$ in the ESI-TOF mass spectrum (**Figure 134**). The UV (**Figure 135**) spectrum was compatible with that expected for cinnamide derivative [λ_{max} (MeOH) 283 nm]. Absorption bands in the infrared (**Figure 136**) spectrum, characteristic of the amide group, was present at 3291, 1648 and 1535 cm^{-1} . These data suggested that this compound belong to the group of bisamides characteristic for *Aglaia* species. This was further confirmed by the following evidences.

The 1H spectrum (**Figure 137**) displayed the characteristic lowfield signals at δ_H 6.8 ($d, J = 15.5$ Hz, H-2''), 7.6 ($d, J = 15.5$ Hz, H-3'') and 7.20-7.50 (5H, m , aromatic proton) of the cinnamyl moiety. The large coupling constant of 15.5 Hz indicated *trans*-double bond at position 2''. Furthermore, methylene proton at δ_H 1.40 (m , H-3), methine proton at δ_H 1.98 (m , H-2) and two methyl groups at δ_H 1.03 ($d, J = 6.5$ Hz, Me-2) and 0.85 ($t, J = 6.5$ Hz, Me-3) showed correlations in the COSY spectrum (**Figure 139**), indicating another acid part of this bisamide as isobutyric acid. The remaining methylenes in the region δ_H 2.02-3.68 and one amide proton at δ_H 5.91 ($d, J = 9.0$ Hz) suggested that the bifunctional amine part would be a cyclic 2-aminopyrrolidine.

The ^{13}C spectrum (**Figure 138** and **Table 19**) also exhibited signals which were consistent with the 1H spectrum, including two amide carbonyl carbons, two olefinic carbons, two methyl groups, four methylenes, six aromatic carbons and two methine carbons. Among two methines one of which appeared at the low field (δ_C 62.50) was assigned for C-2'. This was further confirmed by the HMBC (**Figures 140** and **141**) correlation of δ_H 6.1 (H-2') to δ_C 175.3 (C-1) of amide carbonyl carbon.

On standing in the $CDCl_3$, HAO6 underwent partial epimerization at C-2'. This was apparent in the ^{13}C NMR (**Table 19**) spectrum which exhibited two sets of some of the resonances. The ratio of epimer was about 1:1. The partial racemization at C-2' may easily occur *via* a ring opening mechanism of the 2- amino-substituted pyrrolidine ring (acetal-like N-C-N arrangement) as described previously by Brader *et al.* (1998).

Based on these spectral data and comparison with earlier reported data (Shiengthong *et al.*, 1979), HAO6 was identified as a mixture of odorine (HAO6A) and its 2'-epimer (HAO6B).

The pyrrolidine derivative, odorine, appears to be widely distributed within *Aglaia* and has

already been reported from *A. argentea* Blume and *A. forbesii* King (Dumontet *et al.*, 1996) as well as from *A. elliptica* Blume (syn. *A. harmsiana* Perkins) (Inada *et al.*, 1995). Furthermore, odorine and its 2'-epimer were found to inhibit the growth of the vinblastine-resistant KB cells by enhancing the anticancer activity of vinblastine (Saifah *et al.*, 1993).

2.7 Identification of Compound HAO7

Compound HAO7 was obtained as colorless needle crystals. It has the molecular formula $C_{30}H_{50}O_3$ which was deduced from the peak $[M]^+$ at m/z 458 in the EIMS (**Figure 142**). IR (**Figure 143**) spectrum showed the presence of hydroxyl (3407 cm^{-1}) and carbonyl (1699 cm^{-1}) functionalities.

The ^{13}C APT spectrum (**Figures 145** and **146**) showed 30 carbons consisting of eight methyls, ten methylenes, five methines, six quaternary carbon atoms and one carbonyl carbon. The presence of carbons bearing an oxygen function can be observed in ^{13}C APT spectrum by the signals at δ_{C} 75.47 (C-20), 78.78 (C-24) and 73.14 (C-25). The ^1H -NMR spectrum (**Figure 144**) showed eight tertiary methyls at δ_{H} 0.98 (Me-18), 0.93 (Me-19), 1.15 (Me-21), 1.16 (Me-26), 1.21 (Me-27), 1.07 (Me-28), 1.03 (Me-29) and 0.87 (Me-30), the deshielded methine proton resonated at δ_{H} 3.38 (*dd*, $J = 10.4, 1.5\text{ Hz}$, H-24) and the α -methylene protons adjacent to 3-ketone group in ring A of the tetracyclic system appeared at δ_{H} 2.50 (H-2ax) and 2.44 (H-2eq). These data were typical of the dammarane group of triterpenes (Cascon and Brown, 1972; Asakawa, *et al.*, 1977; Hasan *et al.*, 1984).

The ^1H and ^{13}C NMR chemical shifts of ring A and B of cabraleone, previously isolated from *Aglaia elaeagnoidea* (Fuzzati *et al.*, 1996), *A. tomentosa* (Mohamad *et al.*, 1999) and *A. rubiginosa* (Rivero-Cruz *et al.*, 2004), could be matched closely to HMQC data for HAO7, and the resulting signal assignments (**Table 20**) were consistent with the HMBC and ^1H - ^1H COSY spectra. The similarity of the chemical shifts established that HAO7 has the same carbon skeleton and stereochemistry as cabraleone in the basis tetracyclic system. The assignment of the remaining 20,25-epoxy functionality came from the following evidence.

In the mass spectrum, HAO7 exhibited important fragments at m/z 143 ($C_8H_{15}O_2$) and 125 ($C_8H_{15}O_2 - H_2O$), indicating the existence of one hydroxyl group in the cyclized side chain of epoxy triterpenoid. Cross peak correlations were depicted in HMBC spectrum (**Figure 147**) between Me-21 (δ_{H} 1.15) and C-20 and between both Me-26 (δ_{H} 1.16) and Me-27 (δ_{H} 1.21) and C-25, indicated the location of two oxygenated quaternary carbons appearing at δ 75.47 and 73.14 as C-20 and C-25, respectively.

The observed HBMC (**Figure 147**) correlations from δ_{H} 1.15 (Me-21) to 49.94 (C-17), 75.47 (C-20) and 36.80 (C-22) and from δ_{H} 3.38 (H-24) to 25.64 (C-23) and 73.14 (C-25) clearly indicated the presence of an 20,25-epoxy functionality. Furthermore, inspection of the HMBC spectrum (**Figure 147**) showed that the signal of oxygenated methine proton at δ_{H} 3.38 (H-24) was coupled to δ

73.14 (C-25) of oxygenated quaternary carbon, suggesting the location of a hydroxyl group at C-24. The final consideration was to assign stereochemistry of hydroxyl group at C-24. The coupling constant for H-24 (δ_{H} 3.38) was 10.4 Hz indicated an axial-axial interaction with the axial partner of H₂-23. This would make H-24 axial (β) and the OH at this position therefore equatorial (α).

Based on these data, HAO7 was identified as 20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone which had already been found from *Cistus libanotis* (Rutaceae) (De Pascual Teresa *et al.*, 1982) and *Erythrophleum fordii* (Fabaceae) (Nan, Fang, and Shishan, 2004).

* Waterman and Ampofo, 1985 (in CDCl_3 , 90.56 MHz)

2.8 Identification of Compound EAO1

Compound EAO1 was obtained as colorless needle crystals. The molecular formula $C_{30}H_{52}O_3$ for this compound was deduced from its mass spectrum ($[M]^+$ at m/z 460) (**Figure 148**) in combination with the IR (**Figure 149**) absorption band at 3399 cm^{-1} . The appearance of the fragment peak at m/z 143 strongly suggested that EAO1 would be the dammarane type triterpene with the cyclized side chain of the epoxy type (Cascon and Brown, 1972).

Both ^1H and ^{13}C NMR spectra (**Figures 150-152**) of EAO1 showed two sets of the resonances, suggesting that this compound, although homogeneous by TLC, was in fact a 1:1 mixture of epimers, EAO1A and EAO1B at C-3, judging from the presence of two oxymethine protons at δ_{H} 3.37 (*t*, $J = 3\text{ Hz}$) and 3.17 (*dd*, $J = 11.5, 5\text{ Hz}$) in the ^1H -NMR spectra and the signals resonated at δ_{C} 76.27 and 78.94 of oxymethine carbons in the ^{13}C NMR spectra.

The C-3 epimeric mixture, EAO1A and EAO1B, gave ^1H and ^{13}C NMR spectra which were similar to those of HAO7, but instead of a keto carbonyl, it showed an extra secondary alcohol suggesting its nature as the 3-hydroxy derivative of HAO7. This was confirmed by the following evidences.

The ^1H -NMR spectrum of each component of the mixture, EAO1A and EAO1B (**Figure 150**) showed almost identical signals, including eight tertiary methyls and an oxymethine protons resonated at δ_{H} 3.38 (*dd*, $J = 10.5, 1.3\text{ Hz}$, H-24), while a difference was found in the the splitting patterns and the coupling constants of oxymethine protons at C-3. In EAO1A an oxymethine proton formed triplet with small coupling constant of 3.0 Hz, while in EAO1B the corresponding proton formed double doublet with large coupling constant (11.5 Hz), indicating $3\alpha\text{-OH}$ group in the former and $3\beta\text{-OH}$ group in the latter (Hasan et al., 1984; Waterman and Ampofo, 1985).

All signals of a C-3 epimeric mixture and their connectivity were established by HSQC, HMBC experiments (**Figures 153-157**). The observed HMBC (**Figures 155-157**) correlations from δ_{H} 1.03 (Me-21) to 49.54 (C-17), 75.57 (C-20) and 36.89 (C-22) and from δ_{H} 3.38 (*dd*, 10.5, 1.3, H-24) to 25.60 (C-23) and 73.15 (C-25) suggested an 20,25-epoxy functionality in this molecule. The relative stereochemistry at C-24 was determined from the large coupling constant (10.5 Hz) between H-23ax and H-24 which indicated the β orientation of H-24 (3.38, *dd*, $J = 10.5, 1.3\text{ Hz}$).

Based on the spectral data analysis (**Table 21**), the structure of EAO1 was identified as a mixture of 20*S*,25-epoxy-24*R*-hydroxydammarane $3\alpha\text{-ol}$ (EAO1A) and its C3-epimer, 20*S*,25-epoxy-24*R*-

hydroxydammarane 3 β -ol (EAO1B).

Previous study has revealed the co-occurrence of 20*S*,25-epoxy-24*R*-hydroxydammarane 3 α -ol and its 3-oxodammarane derivative (20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone) in *Cistus libanotis* (Rutaceae) (De Pascual Teresa *et al.*, 1982). However, no information on the biological activities of these compounds is currently available.

20*S*,25-epoxy-24*R*-hydroxydammarane 3 α -ol

3. Bioactivities of Compounds Isolated from *Aglaia forbesii* and *Aglaia oligophylla*

In the search for biologically active constituents of *Aglaia forbesii* and *A. oligophylla*, the hexane, dichloromethane, EtOAc and MeOH extracts of the leaves of *Aglaia forbesii*, as well as the hexane, EtOAc and MeOH extracts of the leaves *A. oligophylla*, were subjected to *in vitro* screenings for their cytotoxic activity against NCI-H187 (human small cell lung cancer), antimalarial activity against *Plasmodium falciparum*, antituberculosis activity against *Mycobacterium tuberculosis* H₃₇Ra and anti-herpes simplex virus type 1 activity.

3.1 Bioactive Compounds from *Aglaia forbesii*

The hexane and dichloromethane extracts of the leaves of *Aglaia forbesii* were found to exhibit antiviral activity against herpes simplex virus type 1. The hexane extract was moderately active (>35-50 % viral inhibition) at the non-cytotoxic concentration of 27.8 µg/ml and the dichloromethane extract was active with IC₅₀ value of 1.9 µg/ml at 38.1 µg/ml. In addition, the dichloromethane extract exhibited antituberculosis activity against *Mycobacterium tuberculosis* H₃₇Ra with MIC value of 25 µg/ml.

Four compounds (lupeol, lupenone, spathulenol and a mixture of β-sitosterol and stigmasterol) were isolated from the hexane extracts of *Aglaia forbesii* leaves, whereas the dichloromethane extract afforded seven compounds, including three cyclopenta[bc]benzopyran flavaglines (desacetylpyramidaglains A, C and D), the cycloartane triterpenoid 23,24,25-trihydroxycycloartan-3-one, two pregnane steroids (2β,3β-dihydroxy-5α-pregn-17(20)-(Z)-en-16-one and 2β,3β-dihydroxy-5α-pregn-17(20)-(E)-en-16-one) and one bisamide (pyramidatine).

All of these isolated compounds, except spathulenol and β-sitosterol/stigmasterol mixture, were evaluated for their biological activities and the results are summarized in **Table 22**.

3.1.1 Cytotoxic Activity

Lupeol, previously reported as cytotoxic against human hepatocellular carcinoma (Hep-G2) and human epidermoid carcinoma (A-431) (Ajaiyeoba *et al.*, 2003), was shown to be cytotoxic to small cell lung cancer cell line (NCI-H187) with IC₅₀ of 6.84 µg/ml.

3.1.2 Antituberculosis Activity

As can be seen from Table 22, all compounds tested, except desacetylpyramidaglains A

and C, exhibited antituberculosis activity against *Mycobacterium tuberculosis* H₃₇Ra. Among these bioactive compounds, desacetylpyramidaglain D and pyramidatine showed strongest activity with MIC value of 25 µg/ml. Up to now, this is the first report on the antibacterial activity of the cyclopenta[bc]benzopyran flavaglines.

3.1.3 Anti HSV-1 Activity

The cycloartane triterpenoid, 23,24,25-trihydroxycycloartan-3-one, was shown to be moderately active against Herpes simplex virus type 1 at the non-cytotoxic concentration of 50 µg/ml. Other compounds subjected to this test were inactive, with the exception of 2β,3β-dihydroxy-5α-pregn-17(20)-(E)-en-16-one and desacetylpyramidaglain D, which were weakly active at the non-cytotoxic concentration of 50 µg/ml.

3.2 Bioactive Compounds from *Aglaia oligophylla*

Preliminary bioactivity evaluation revealed that the hexane and EtOAc extracts of the leaves of *Aglaia oligophylla* exhibited strong cytotoxic activity against NCI-H187 cancer cell line at the IC₅₀ values of 3.86 and 4.22 µg/ml, respectively, as well as antimalarial activity against *Plasmodium falciparum*, KI stain, at the IC₅₀ values of 2.5 and 5.1 µg/ml, respectively. Furthermore, these two also displayed anti-HSV1 activity, of which the hexane extract was weakly active at 2 µg/ml and the EtOAc extract was moderately active at 23.5 µg/ml. The latter extract also showed antimycobacterial activity against *Mycobacterium tuberculosis* with the MIC value of 100 µg/ml.

Chemical investigation of the hexane extract of the leaves led to the isolation of six dammarane-type triterpenoids (dipterocarpol, a mixture of ocotillone and cabraleone, ocotillo-II, 20*S*,24*S*-dihydroxydammar-25-en-3-one, and 20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone), a cyclopenta[*b*]benzofuran flavagline (rocaglaol) and a mixture of bisamide (odorine and 2'-epiodorine), while the EtOAc extract afforded a mixture of 20*S*,25-epoxy-24*R*-hydroxydammar-3α-ol and its C-3 epimer.

The results of the bioactivity evaluation of all of these isolated compounds except rocaglaol are presented in **Table 23**.

3.2.1 Cytotoxic activity

As shown in Table 23, none of these compounds were cytotoxic. The cytotoxic activity of the crude extract of *Aglaia oligophylla* might therefore be attributed to rocaglaol, previously reported as cytotoxic (Ishibashi *et al.*, 1993; Dumontet *et al.*, 1996; Mulholland and Nadoo, 1998).

3.2.2 Antituberculosis activity

The dammarane type triterpenoid (a mixture of 20*S*,25-epoxy-24*R*-hydroxydammaran-3α-ol and its C-3 epimer) and a mixture of bisamide odorine and 2'-epiodorine, were able to inhibit the growth of *Mycobacterium tuberculosis* with MIC values of 50 and 200 µg/ml, respectively.

3.2.3 Anti HSV-1 activity

In this study, no anti HSV-1 activity was detected for any of these tested compounds.

3.2.4 Antimalarial activity

All the compounds tested appeared to be devoid of antimalarial activity against *Plasmodium falciparum*, KI stain. Since the cyclopenta[*b*]benzofuran flavagline, rocaglaol, was previously found to

exhibit significant insecticidal (Ishibashi *et al.*, 1993) and cytotoxic (Rivero-Cruz *et al.*, 2004) activity, it might be responsible for the antimalarial activity of the crude extract.

Table 23. Bioactivities of isolated compounds from *Aglaia oligophylla*

| Compound | Anti HSV-1 | Anti TB | Antimalarial | Cytotoxicity IC ₅₀ (µg/ml) | |
|---|-----------------------------|----------------|-----------------------------|---------------------------------------|-----------|
| | IC ₅₀ (µg/ml) | MIC (µg/ml) | EC ₅₀ (µg/ml) | NCI-H187 | Vero cell |
| Dipterocarpol | inactive | inactive | inactive | inactive | > 50 |
| Ocotillone/cabraleone | inactive | inactive | inactive | inactive | > 50 |
| Ocotillol II | inactive | inactive | inactive | inactive | > 50 |

CHAPTER V

CONCLUSION

Chromatographic separation of the n-hexane fraction of the methanolic leaf extract of *Aglaia forbesii* led to the isolation of the sesquiterpene spathulenol, the ubiquitous triterpenoids lupeol and lupenone, and a mixture of β -sitosterol and stigmasterol. The CH_2Cl_2 fraction yielded three new cyclopenta[*bc*]benzopyran flavaglines, named desacetylpyramidaglains A, C, and D, and a new triterpene, 23,24,25-trihydroxycycloartan-3-one, together with two rare pregnane steroids, 2 β ,3 β -dihydroxy-5 α -pregn-17(*Z*)-en-16-one and 2 β ,3 β -dihydroxy-5 α -pregn-17(*E*)-en-16-one, and the bisamide pyramidatine.

Similar study on another meliaceous plant, *Aglaia oligophylla* Miq, afforded eleven of its constituents including eight dammarane-type triterpenoids (dipterocarpol, a mixture of ocotillone and cabraleone, ocotillo-II, 20*S*,24*S*-dihydroxydammar-25-en-3-one, 20*S*,25-epoxy-24*R*-hydroxy-3-dammaranone, and a mixture of 20*S*,25-epoxy-24*R*-hydroxydammar-3 α -ol and its C-3 epimer (20*S*,25-epoxy-24*R*-hydroxydammar-3 β -ol), a cyclopenta[*b*]benzofuran flavagline (rocaglaol) and a mixture of two pyrrolidine-type bisamides, odorine and 2'-epi-odorine.

All of the compounds from *Aglaia forbesii*, except desacetylpyramidaglains A and C, exhibited anti-TB activity, of which desacetylpyramidaglain D and pyramidatine showed the highest activity with MIC value of 25 $\mu\text{g/ml}$. 23,24,25-Trihydroxycycloartan -3-one, desacetylpyramidaglain D and 2 β ,3 β -dihydroxy-5 α -pregn-17(20)-(*E*)-en-16-one were shown to be moderately to weakly active against HSV-1 at the non-cytotoxic concentration of 50 $\mu\text{g/ml}$. Lupeol was moderately cytotoxic against NCI-H187 cancer cell line at the IC_{50} value of 6.84 $\mu\text{g/ml}$. However, all of the compounds isolated from *Aglaia oligophylla* were shown to be devoid of any bioactivity except 20*S*,25-epoxy-24*R*-hydroxydammar-3-ol and the mixture of odorine and 2'-epi-odorine which exhibited anti-TB activity with the MIC values of 50 and 200 $\mu\text{g/ml}$, respectively.

Based on present knowledge, the very characteristic bisamides and flavaglines occur only in *Aglaia* species. Hence, these natural products may be useful as chemotaxonomic markers for the genus *Aglaia*. In accordance with previous studies (Brader *et al.*, 1998; Wang, *et al.*, 2004), we obtained both

flavaglines and bisamide derivatives in addition to other compounds from the leaves of these two species of *Aglaia*. The results obtained in this study reinforce the view that a significant taxonomic contribution can also be expected from phytochemical characters.
