KEYWORDS : *Wolffia globosa* / KHAI-NAM / WATERMEAL / DUCKWEED / OPTIMAL CONDITION / PRODUCTION /

NISACHOL RUEKAEWMA: OPTIMAL CONDITIONS FOR PRODUCTION OF KHAI-NAM *Wolffia globosa*. ADVISOR: ASSOC. PROF. SOMKIAT PIYATIRATITIVORAKUL, Ph.D., CO-ADVISOR: SORAWIT POWTONGSOOK, Ph.D., 121 pp.

Study on optimal conditions for the production of Khai-nam (water meal), *Wolffia globosa*, were carried out. Khai-nam was collected from the natural pond in Mueang district, Sakon Nakhon province, Thailand. According to morphological investigation, it was identified as *Wolffia globosa*. Under natural condition, asexual reproduction of Khai-nam took approximately 96 hours or 4 days for each generation. Highest density of *W. globosa* in natural pond was 65.18 g dry weight m^{-2} in July and the lowest density was 2.45 g dry weight m^{-2} in February. The highest productivity, 1.05 g dry weight $m^{-2}d^{-1}$, was found in June and no growth of Khai-nam was detected in August. Nutritional analysis of *W. globosa* from native pond was 33.3% protein with complete essential amino acids profile, 5.0% fat and 10.4% crude fiber. Bacterial analysis showed that Khai-nam from natural source had low bacterial contamination and therefore accepted for human consumption. Growth optimization of *W. globosa* was carried out under laboratory conditions. It was found that Hutner's medium provided high yield of 0.18±0.04 fronds $ml^{-1}d^{-1}$ with 17.37±2.9 days of life span. With outdoor cultivation, high light intensity during day time did not affect photosynthesis efficiency (quantum yield of PSII) measure by chlorophyll fluorescence technique but high temperature at 40 ^{o}C significantly reduced photosynthesis efficiency. The optimum pH for *W. globosa* was between 5 and 7 and the optimum initial density for *W. globosa* cultivation was 5 to 20% water surface area coverage. A factorial experiment on light intensity, initial pH and initial density on growth performance and quality of *W. globosa* indicated that 10,000 lux light intensity, initial pH of 6 and 15% initial density provided the highest yield. Finally, five outdoor culture systems for production of *W. globosa* were evaluated. The culture systems included (1) static tank, (2) vertical aeration tank, (3) horizontal surface agitation tank, (4) tank with top water spraying, and (5) layer culturing system with top water spraying. The cultivation period was 28 days. The results showed that the tank with horizontal circulation provided the highest yield of 1.52±0.04 g DW m^{-2} d^{-1}. The biomass produced had 48.2% protein with complete essential amino acids, 9.6% fat, and 14.5% crude fiber with low bacterial contamination.

ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to my advisor Assoc. Prof. Somkiat Piyatiratitivorakul and Dr. Sorawit Powtongsook for their advices, Assoc. Prof. Sirirat Rengpipat, Assoc. Prof. Thaithaworn Lirdwitayaprasit, Dr. Yupyn Chintapakorn and Assoc. Prof. Sukhoom Rowchi kindly serve as the thesis committee.

My acknowledgement is also expressed to Mr. Harnchoke Butweingpun, lecturer, from Sakon Nakhon Technical College for his useful suggestions and constructions about *Wolffia* culture systems; Prof. E. Landolt kindly supplied me the information of *Wolffia.*

I would like to thank you Miss Iing-on Tongcomdee, Miss Puncharas Gorcharoenwat, Mr. Dusit Srivilai and friends in Plankton Laboratory, Dept. Marine Science throughout Program in Biotechnology for their help in laboratory work and everything, moreover, Miss Supaporn Kodtha and Miss Srisuwan Huadkuntha from Sakon Nakhon Inland Fisheries Research and Development Center for the water analysis.

Throughout the long period of my doctoral program my parents and my parents in law have assisted me both financially and emotionally, moreover, I greatly appreciate to Miss Prapit Ruekaewma, sister in law, for take care our family and everything. My strongest and most important supporter and champion and will always be my husband Mr. Pramook Ruekaewma, who stuck by me through thick and thin and whose unfailing support made this dissertation possible. This dissertation is as much his achievement as mine. Last but not least I need to thank my daughter Chollathip Ruekaewma who does not complain about my absences and love me for who I am.

This research was supported by Rajamagala University of Technology Isan, Thai Government Scholarship in the Area of Science and Technology, NSTDA, Ministry of Science and Technology and The 90th Anniversary of Chulalongkorn University Fund (Ratchadaphiseksomphot Endownment Fund).

CHAPTER I

INTRODUCTION

Development of new foods is vital to the needs of rapid expanding in Asia because of rapid human population growth. *Wolffia* spp., watermeal or duckweed, is an aquatic plant generally found throughout Thailand and the neighbor countries. *Wolffia arrhiza* is used as food ingredient by Burmese, Laotian and Thai especially in the northeast and northern of Thailand. Watermeal or Khai-nam in Thai is an oval shape plant floating on pond water surface. Khai-nam is generally regarded as poor people's food and has attracted little attention as a potentially significant source of human food (Bhanthumnavin and McGary, 1971).

Furthermore, *W. arrhiza* exhibits high growth rate and consequently absorbs large amounts of nitrogen and phosphorus and its vegetative frond contains 40% protein on dry weight (Fujita, Mori and Kodera, 1999). Moreover, it may be feasible to use *W. arrhiza* and *W. globosa* to produce high protein animal feed (Naskar et al., 1986; Chantiratikul et al., 2010; Chantiratikul and Chumpawadee, 2011). *Wolffia* spp. also has a potential for a utilization and treatment of wastewater (Hillman and Culley, 1978; Edward et al., 1992).

In addition, researchers are using these plants to study basic plant development, plant biochemistry, photosynthesis, toxicity of hazardous substances, and much more.

Genetic engineers are cloning and modifying *Wolffia* spp. genes to inexpensively produce pharmaceutical products. Environmental scientists are using *Wolffia* spp. to remove unwanted substances from water (Cross, 2006: online). Although *Wolffia* spp. has been widely studied, the hygiene mass production of *Wolffia* spp. has received only little attention. In this research, we elucidate the effects of light intensity, temperature, pH, density and nutrients on growth and quality of *Wolffia* sp. and a suitable culture system for hygiene mass production of *Wolffia* sp. will be developed.

The objectives of this research are: 1) To study effect of light intensity, temperature, pH, density and nutrient on the performance of growth and quality of *Wolffia* sp. and 2) To develop a suitable culture system for the mass production of *Wolffia* sp. for human consumption.

CHAPTER II

LITERATURE REVIEW

INTRODUCTION

Wolffia is a genus of 11 species which is the smallest flowering plant on Earth. Some *Wolffia* species are shown in Figure 2-1., 2-2. and 2-3. Commonly called watermeal, these aquatic plants resemble specks of cornmeal floating on the water. *Wolffia* spp. are free-floating frond, green or yellow-green in color, and no roots. The flower is produced in a depression on the top surface of the plant body. It has one stamen and one pistil. Individuals often float together in pairs or form floating mats with related plants, such as *Lemna* spp. and *Spirodela* spp. (Figure 2-4.).

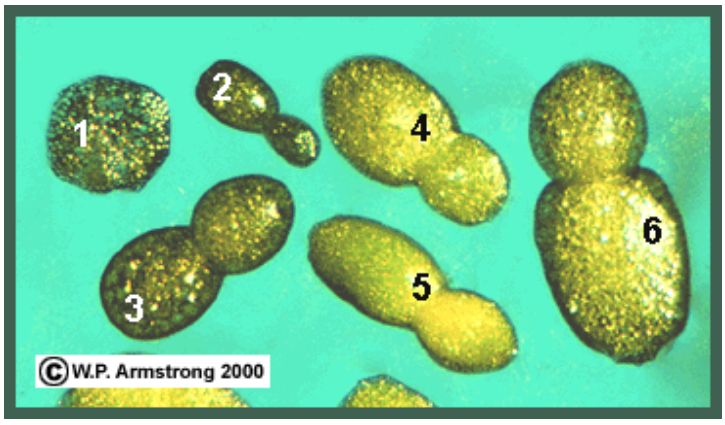

Figure 2-1. Dorsal view of six *Wolffia* species: 1. *W. microscopica* (India); 2. *W. globosa*; 3. *W. columbiana*; 4. *W. brasilliensis*; 5. *W. borealis*; 6. *W. arrhiza* (Germany) (Armstrong, 2000: online)

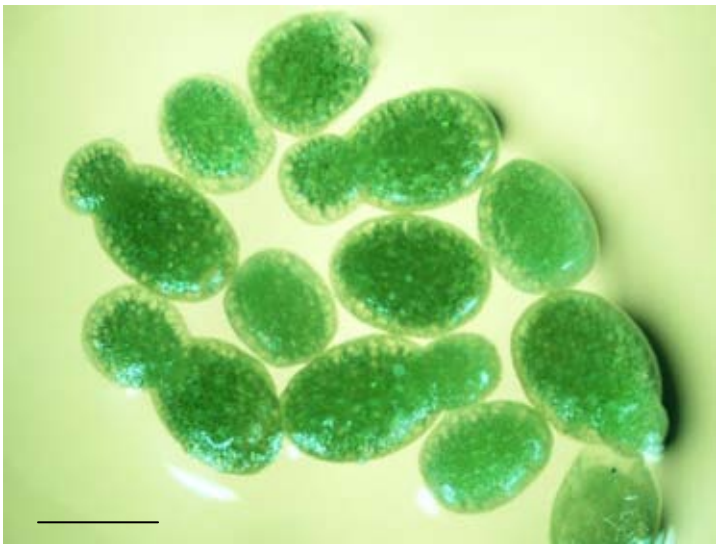

Figure 2-2. Dense population of *Wolffia* sp. at a natural pond in Mueang district, Sakon Nakhon province, Bar = 0.5 mm

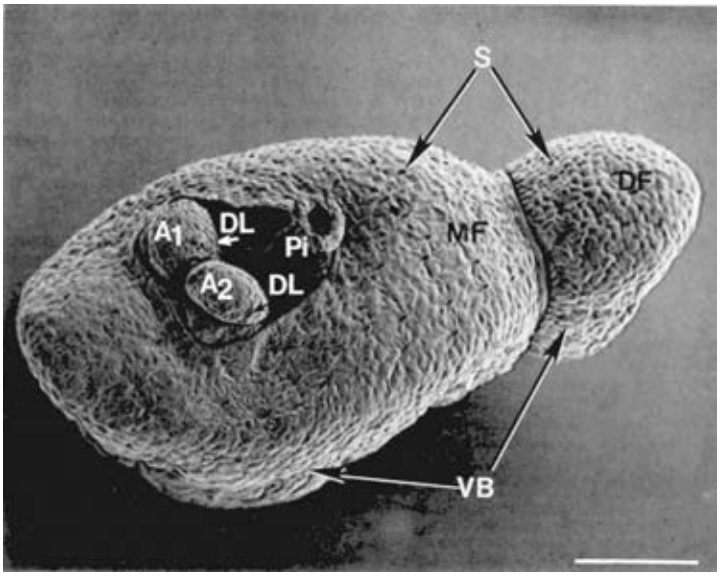

Figure 2-3. SEM of a two frond colony of *W. australiana* showing mother frond (MF), daughter frond (DF), stoma (S), and ventral bulge (VB). The mature flower consists of a pistil (Pi) and the two lobes of the anther labeled as A1 and A2. Each anther lobe has a dehiscence Line (DL). Bar=0.25 mm (Bernard, Bernard and Denny, 1990)

Most *Wolffia* species have a very wide distribution across several continents (Wikipedia, 2009: online). *Wolffia* is classified as:

Kingdom:	Plantae
(unranked):	Angiosperms
(unranked):	Monocots
Order:	Alismatales
Family:	Araceae
Subfamily:	Lemnoideae
Tribe:	Wolffieae
Genus:	***Wolffia***
Species:	*Wolffia angusta*
	Wolffia arrhiza
	Wolffia australiana
	Wolffia borealis
	Wolffia brasiliensis
	Wolffia columbiana
	Wolffia cylindracea
	Wolffia elongata
	Wolffia globosa
	Wolffia microscopica
	Wolffia neglecta

Figure 2-4. Floating *Wolffia* at surface of quiet a stream, often mixed with other Lemnaceae and aquatic plants such as *Lemna* spp. and *Spirodela* spp. (Armstrong, 2005: online)

Bhanthumnavin and McGarry (1971) observed and analyzed native methods of cultivating *W. arrhiza*. They reported protein, fat and crude fiber contents as 19.8%, 5.0% and 13.3% of dry weight, respectively. Moreover, in 1999, Jairakphan reported protein, fat and crude fiber contents of *W. arrhiza* collected from natural pond were 20.15%, 2.43% and 14.72%, respectively. Essential amino acid profile of the protein concentrate was; aspartic 1.21, threonine 0.64, serine 0.57, glutamic 1.67, proline 0.67, glycine 0.83, alanine 1.60, cystine 0.10, valine 0.94, methionine 0.20, isoleucine 0.69, leucine 1.30, tyrosine 0.37, phenylalanine 0.76, histidine 0.31, lysine 0.75, arginine 0.80, tryptophan 0.20 (g/100g of protein).

In another study reported protein, fat and crude fiber contents of *W. columblana* collected from anaerobic dairy waste lagoons on the LSU campus, the lagoons contained from 20 to 40 mg l^{-1} of TKN during the collection period. There were 44.7% protein, 6.6% fat and 11% crude fiber and essential amino acid profile of

the protein concentrate was listed; aspartic 5.63, threonine 2.55, serine 2.28, glutamic 5.76, proline 2.41, glycine 3.04, alanine 3.75, valine 3.49, methionine 0.87, isoleucine 3.06, leucine 5.83, tyrosine 2.17, phenylalanine 3.60, histidine 1.18, lysine 3.37, arginine 3.78 (g/100g of protein) (Rusoff, Blakeney and Culley, 1980).

ASEXUAL REPRODUCTION OF *Wolffia*

In laboratory condition, *W. arrhiza* has a vegetative reproduction by budding, with a generation time of approximately 4 days (Sakdisuwan, 1967; Vacharabhaya, 1969)

Bernard et al. (1990) reported that vegetative reproduction of *W. australiana* was by budding of new frond from one basal budding cavity. As many as two second generation (daughter) fronds, a third generation (granddaughter) frond and stipes of former second generation fronds present at one time were found in a budding cavity (Figure 2-5.). A heart shaped opening was found in the dorsal flower cavity and a pistil and a single stamen with a bilobed anther was found in the flower, having a red dehiscence line in each lobe. There was no significant difference in life span or fronds number produced by the three generations of parents studied. Life span were 17 days and 11 fronds were produced. Frond size at detachment decreased with increased age of the parent but all experimental plants continued to grow after detachment although small, late fronds did not grow as large as those produced early in the life.

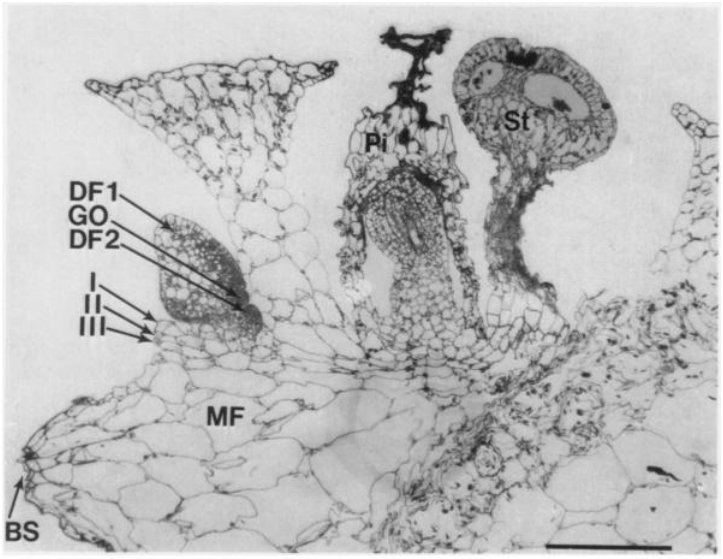

Figure 2-5. Light micrograph of a longitudinal section of *W. australiana* showing pistil (Pi) and stamen (St) in flower cavity. Daughter fronds (DF1 and DF2) and granddaughter (GO) as well as stipes (I, II and III) of three earlier fronds can be seen in the budding cavity. Note bud detachment (BS) area where mother frond (MF) detached from its parent, Bar = 0.1 mm (Bernard et al., 1990)

Lemon, Posluszny and Husband (2001) reported rate of vegetative reproduction development in duckweeds (Lemnaceae) *W. borealis*, by measuring the number of daughter fronds produced over the life span of mother fronds. Life span of *W. borealis* was 15.8 days and produced 9.8 daughter fronds (number), thus *W. borealis* exhibited the reproductive rate of 0.62 fronds per day. Vegetative reproduction production in the Lemnaceae forms a continuum from *Wolffia*, which develops relatively small (0.5–1.5 mm) and numerous propagules are released before maturity.

FACTORS EFFECTING ON *Wolffia*

Duckweed is cultured in axenic (sterile) conditions using chemically defined media under artificial lights and growth rates were recorded that far exceeded growth rates measured under natural conditions. Duckweed populations are limited mostly by light, temperature and nutrients (Hillman, 1961). Temperature is the most important factors determining growth rates of free floating macrophytes in the field (Heide et al., 2006). Moreover, crowding is also an important factor in limitation of duckweed growth (Driever, Van Nes and Roijackers, 2005; Frederic et al., 2006).

Cultivating *W. arrhiza* was observed in native methods and analyzed. Small scale cultivation by rain fed was carried out by villagers living near provincial urban centers in northern Thailand. The pH of water was between 6.5 to 7.0 and shaded by bamboo groves. *W. arrhiza* remains in its edible vegetative from November to July and inedible sexually reproducing from August to October. On 9 months of productivity the calculated annual yield was 265 tons wet wt ha^{-1}or 10.5 tons dry wt ha^{-1}(Bhanthumnavin and McGarry, 1971).

Naskar et al. (1986) reported that sewage effluent is rich in nutrients and therefore can serve as a culture medium for the duckweed *W. arrhiza*. Growth rate and total biomass production of *W. arrhiza* were investigated. With 100% sewage effluent the total extrapolated production of duckweed was 100.5 tons $ha^{-1}year^{-1}$.

W. arrhiza (Landolt, 1986) is a small circular floating weed with a size of 1 mm in length and lives in tropical and subtropical lakes and marshes. In summer, the vegetative frond of *W. arrhiza* grows quickly and absorbs large amounts of nutrients. In autumn and winter, however, the frond changes to a resting form, called “turion”.

The turion contains a large amount of starch and sinks to the bottom due to the change in its density. The vegetative frond contains a large amount of protein but a small amount of starch. Turions were induced effectively under a high plant density, an ample quantity of light and a long illumination period. Turions can be easily induced from vegetative frond artificially under a high plant density and high light strength using a culture solution with a low nutrient concentration, as in water treated by cultivation of the vegetative frond (Fujita et al., 1999).

Suppadit et al. (2008) and Suppadit (2011) reported that a biomass of 12 g of *W. arrhiza* $l^{-1}$of shrimp farm and quail farm effluent with treatment period of 30 days provided the best conditions for the growth of *W. arrhiza*.

N-P-K fertilizer (16 -16- 16) at 100 mg l^{-1} was added with tap water for *W. arrhiza* cultivation and adjusted pH at 5-6 under opened building at light intensity more than 5,000 lux throughout 30 days- culture. 2 kg wet wt m^{-2} were found in this study. Beta-carotene was 600 mg wet wt m^{-2} in 24 days- culture (Panwanidumrong, 2009).

The biomass production of duckweed on the tank was conducted with two treatments. With a TN concentration of about 2 mg l^{-1} in both treatment, the first treatment was the duckweed grew on the water surface of three round tanks with a radius of 0.9 m and a height of 0.9 m. the water surface area was 2.54 m^{-2} in each tank. The second treatment was that duckweed grew in three 30x30 cm square frame made of 10 cm diameter PVC pipe and those PVC square frames were floating in another tank with same size as those used in the first treatment. The daily growth rates of duckweed in three big tanks and three small square PVC frames were 0.099 kg wet wt

m^{-2} (361 tons wet wt ha^{-1} annually) and 0.127 kg wet wt m^{-2} (464 tons wet wt ha^{-1} annually), respectively (Fedler and Duan, 2011).

Most bioregenerative life support systems, BLSS, are based on gravitropic higher plants which exhibit growth and seed generation disturbances in microgravity. When used for a lunar or martial base the reduced gravity may induce a decreased productivity in comparison to Earth. Therefore, the implementation of aquatic biomass production modules in higher plant and/or hybrid BLSS may compensate for this and offer, in addition, the possibility to produce animal protein for human nutrition. These are plant production bioreactors for the species mentioned above and another suitable candidate, the lemnacean (duckweed) species, *W. arrhiza.* Moreover, combined intensive aquaculture systems with a closed food loop between herbivorous fishes and aquatic and land plants are being developed which may be suitable for integration into a BLSS of higher complexity (Bluem and Paris, 2001).

PRACTICAL APPLICATIONS OF *Wolffia*

As a new source of inexpensive protein

It is known that *W. arrhiza* Wimm. was used as a vegetable by Burmese, Laotians and people in the northeast and northern of Thailand for many generations. The name in Thai, Khai-nam, suggests the oval shape of the plant (length 1.5 mm, width 1.0 mm). Khai-nam is generally regarded as poor people's food and has attracted little attention as a potentially significant source of human food (Bhanthumnavin and McGarry,1971).

The value of duckweed as a source of feed for fish and poultry has been promoted by the World Bank, especially in developing countries (Skillicorn, Spira and Journey, 1993). Researcher in Thailand demonstrated the value of using *W. globosa* as a dietary protein replacement on performance and carcass characteristics in broilers (Chantiratikul et al., 2010). *W. arrhiza* also has potential as a feed ingredient of fish farming (Naskar et al., 1986). Its amino acid composition is similar to those of animal protein than plant protein, having high lysine and methionine content, two amino acids normally deficient in plant products (Dewanji, 1993). Finally, dried duckweed can provide vitamins, minerals and pigments such as beta carotene in livestock diets, reducing the need to add these compounds to rations and thus the feed producer money.

Perhaps the most promising use of duckweed is as a feed for pond fish such as carp and tilapia, *W. arrhiza* alone supported the growth of two species of Indian carp and four species of Chinese carps as well as one species of barb (Naskar et al., 1986). Mature poultry can utilize dried duckweed as a partial substitute for vegetable protein such as soybean meal in cereal grain based diets.

As an alternative means of wastewater treatment

Considerable work was done in the 1970's and 1980's on the use of duckweed genera, especially *lemna*, as a means of treating wastewater of both agricultural and domestic origin. A part of a facultative treatment system, duckweed can cover treatment ponds and reduce the growth of algae in these ponds as well as reduce nitrogen in the effluent from these ponds through ammonia uptake and denitrification (Alaerts, Mahbubar and Kelderman, 1996). Duckweed can also be part of constructed

wetland systems, either as a component of a wetland receiving wastewater of as plants that polish nutrients from wetland treated effluents.

Researcher used *Wolffia* for treatment on effluent from shrimp farms and quail farms (Suppadit et al., 2008; Suppadit, 2011) and guidelines for the use of duckweed to remove ammonia and phosphorus from effluent from an algae culture system were given by Koles, Petrell and Bagnall (1987).

As an inexpensive and accurate way of toxicity testing

Due to its small size and ease of growth, duckweed species make ideal organisms for toxicity testing (Lakatos et al., 1993). Duckweed species have been used to test the toxicity of oils (King and Coley, 1985) and *Wolffia* was used as bioindicator of zinc and cooper contamination in natural water resources (Pla-on, 2005).

CHAPTER III

MATERIALS AND METHODS

The optimized conditions for production of Khai-nam, *Wolffia* sp., were carried out into 3 parts, i.e. (1) biology investigation of Khai-nam, (2) effects of culture media, light intensity, temperature, initial pH and initial density on Khai-nam production in laboratory and (3) outdoor mass culture systems for Khai-nam. The laboratory experiments were conducted at Marine Plankton Culture Laboratory, Department of Marine Science, Chulalongkorn University, Bangkok. The outdoor mass culture systems were conducted at Town Tan Tor agricultural farm, Mueang district, Sakon Nakhon province.

BIOLOGICAL INVESTIGATION OF KHAI-NAM

The biological investigation of Khai-nam, *Wolffia* sp., in nature was carried out in 4 steps, i.e. (1) species identification of Khai-nam isolated from natural pond, (2) investigation of asexual reproduction in Khai-nam, (3) estimating production rate in natural pond and (4) proximate analysis and microbial determination in Khai-nam. The biological investigation of Khai-nam was conducted in a natural pond at Mueang district, Sakon Nakhon province.

Identification Khai-nam *Wolffia* sp. from the natural pond

Khai-nam, watermeal, *Wolffia* sp. was collected from a small pond in Mueang district, Sakon Nakhon province and identified following Landolt (1994) (Figure 3-1., 3-2., 3-3.).

Key to the species (Landolt, 1994)

- Surface of the fronds 11/3-21/2 times as long as wide, 11/2-3 times as deep as wide, with the greatest width at the surface of the water (nearly no translucent edge visible from above); stigma with pigment cells

  - Fronds mostly > 0.9 mm long, with 50-120 stomata…..……....*W. australiana*

  - Fronds mostly < 0.9 mm long, with 8-20 stomata

    - Fronds whitish green at the surface with intensely green margins,

      2 - 3 times as deep as wide……...……...*W. angusta*

    - Fronds intensely green at the surface without green colored margins,

      11/2-2 times as deep as wide……...……..… *W. neglecta*

- Surface of the fronds 1-12/3 times as long as wide, 3/4-11/2 as deep as wide, with the greatest width below the surface of the water (at least laterally a translucent edge visible from above); stigma without pigment cells

  - Fronds intensely green and mostly shiny at the surface,

    with mostly >30 stomata.....…… *W. arrhiza*

  - Fronds not shiny, pale green to rather intensely green, with < 30 stomata

    - Fronds mostly < 0.6 mm wide, 11/4-12/3 as long as wide

      - Fronds with no translucent edge at the tip,

        with 15-30 stomata……..…… *W. cylindracea*

      - Fronds with distinct translucent edge at the tip, mostly

        < 20 stomata……..…… *W. globosa*

    - Fronds mostly > 0.6 mm wide, 1-11/3 as long as wide. *W. columbiana*

Asexual reproduction of Khai-nam *W. globosa*

The collected frond of *W. globosa* at natural pond in Meuang district, Sakon Nakhon province was examined under a light microscopy and photographs were taken every 6 hours to find a releasing stage of the daughter frond from single mother frond.

Production rate of Khai-nam *W. globosa* in natural pond

W. globosa at natural pond (30 x 60 x 1.5 m) in Meuang district, Sakon Nakhon province (N 17^{o} 08. 021′, E 104^{o} 06.780′) (Figure 3-4.) was random collected around the pond.

A strainer, which was made from iron structure (diameter 32 cm) and cover with filter cloth, was used for *W. globosa* collection. When expanded *W. globosa* full the pond, sample was random collected 10 points around the pond. The strainer was dipped under water surface area after 10-15 minute lifting the strainer for the sample collection at water surface area. If the blow sample go to total up at pond corner by the wind, *W. globosa* was collected of all in the pond. The dry weight was determined. Dry weight was determined by drying *W. globosa* for 24 hours in an oven at 70 ^{o}C (Driever et al., 2005).

The experiment was run every month in a year period. The environment conditions of light intensity (measured by luxmeter), light period, temperature (measured by thermometer), pH (measured by pH meter), dissolved oxygen, ammonia, nitrite, alkaline and hardness were recorded. For dissolved oxygen, ammonia, nitrite, alkaline and hardness were analyzed following APHA (1995)

Figure 3-4. The nature pond filled with *W. globosa*

Proximate analysis and microbial determination

W. globosa was collected locally at a small pond in Mueang district, Sakon Nakhon province, during maximum density in 2009, July, and transferred to the laboratory for proximate analysis (AOAC, 2005, 2008), amino acid profile (Petritis, Elfakir and Dreux, 2002) and microbial determination (USFDA/CFSAN/BAM, 2009: online, Chapter 3, 4, 12).

FACTORS EFFECTING ON KHAI-NAM *W. globosa* PRODUCTION

The factors effecting on the growth of *W. globosa*, in the laboratory were carried out in 6 steps, i.e. (1) culture media experiment for *W. globosa*, (2) effect of light intensity on photosynthesis effect of *W. globosa*, (3) effect of temperature on

photosynthesis effect of *W. globosa*, (4) effect of initial pH on the growth of *W. globosa*, (5) effect of initial density of *W. globosa* and (6) a factorial experiment on light intensity, initial pH and initial density on the growth and quality of *W. globosa*. The laboratory experiments were conducted at Marine Plankton Culture laboratory, Department of Marine Science, Chulalongkorn University, Bangkok.

Culture media experiment

Four culture media were selected for the study. There were natural pond-water medium from pond 1 and 2 where *W. globosa* has been found at Mueang district, Sakon Nakhon province; modified Hoagland's medium (Sakdisuwan, 1967) (Appendix 1.); modified Hutner's media (Hutner, 1953) (Appendix 2.) and distilled water as a control.

W. globosa collected locally at a small pond in Mueang district, Sakon Nakhon province was cleaned by placing in a 20% bleach (sodium hypochlorite) solution for several seconds to a minute, then rinsed with sterile water (Rains, 1993) and transferred into the above 5 media. Individual frond of *W. globosa* was grown in 24 well plates with 2 ml of each media (Figure 3-5.) at controlled temperature 25 °C with 12 hours photoperiod of 4000 lux light intensity.

When the mother fronds (G0) had produced a daughter frond (G1), the daughter frond was removed from the mother frond after recording the frond size and the period of frond generation. The first daughter frond was transferred to new culture medium which was the same as mother frond medium. The daughter frond had produced a granddaughter frond (G2), the first granddaughter frond was removed from the daughter frond then recording the frond size and the period of frond generation.

The first granddaughter frond was transferred to new culture medium which was the same as mother frond medium. The granddaughter frond had produced a great-granddaughter frond (G3), the first great-granddaughter frond was removed from the granddaughter frond then recording the frond size and the period of frond generation. The daughter frond number and the life span of each mother frond were recorded.

Production rate of each culture medium was calculated by total number of daughter frond divided by the life span of the mother frond (Lemon et al., 2001) and divided by the culture area.

All data were analyzed using descriptive statistics and analysis of variance (ANOVA) followed by Duncan's multiple range comparison tests at $p \geq 0.05$.

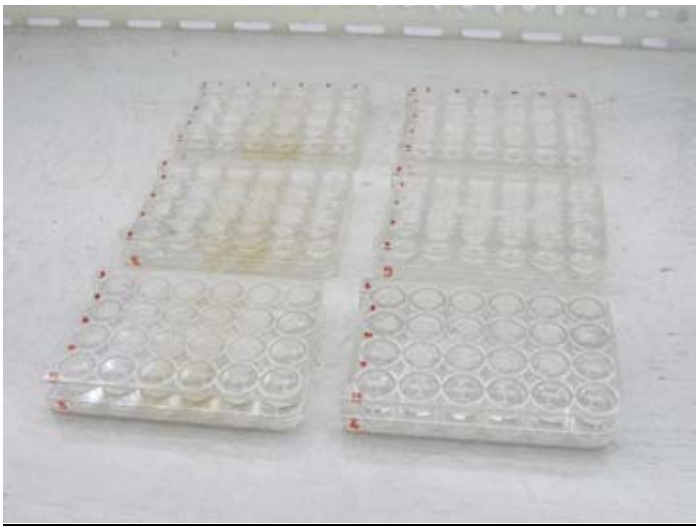

Figure 3-5. *W. globosa* cultivation in 24 wells tissue cultured plates, only individual frond was cultured in each well.

Effect of light intensity on photosynthesis of Khai-nam *W. globosa*

Effect of light intensity on photosynthesis of *W. globosa* was done by cultivating in Hutner's medium. Approximately $5x10^7$ fronds of *W. globosa* were placed in a quadrilateral plastic box (0.38x0.58x0.1 m) contained 22 l of Hutner's medium and exposed with various light intensity of natural light. Photosynthesis efficiency was measured using chlorophyll fluorescence technique (Kitajima and Butler, 1975) by Fv/Fm, where Fv meant variable fluorescence and Fm meant maximum fluorescence. The *W. globosa* was measured at 7.00 am, 9.00 am, 11.00 am, 13.00 pm, 15.00 pm and 17.00 pm.

Fv/Fm meant optimal quantum yield were calculated by following equation (Kitajima and Butler, 1975).

$$Fv/Fm = (Fm - Fo) / Fm$$

Where Fo is the dark adapted initial minimum fluorescence, Fm is maximal fluorescence measured during the first saturation pulse after dark adaptation.

Effect of temperature on photosynthesis of Khai-nam *W. globosa*

W. globosa was cultured in Hutner's medium as the technique in light intensity experiment and adjusted to the tested temperature of 10, 15, 20, 25, 30, 35 and 40^oC. Approximately $1x10^5$ fronds of *W. globosa* were placed in tube containing 5 ml of Hutner's medium, the tubes then were placed in plastic boxes (25x35x20 cm) and about 15 cm of water was added for temperature control by an electrical heater for the tested temperature of 20, 25, 30, 35 and 40^oC (Figure 3-6.). Temperature of the water

was checked by a thermometer. The other temperature of 10 and 15 ^{o}C were carried out in the incubator. The experiment was run under a light intensity of 5000 lux after 3 hours of acclimation photosynthesis was determined. Photosynthesis efficiency was measured using chlorophyll fluorescence technique by Fv/Fm (Kitajima and Butler, 1975).

Figure 3-6. Temperature control unit for *W. globosa* grown in various temperatures for photosynthesis study

Effect of initial pH on growth of Khai-nam *W. globosa*

Effect of seven initial pH values; 4, 5, 6, 7, 8, 9 and 10 were investigated on growth and size of *W. globosa*. Hutner's medium was prepared and adjusted to the tested pH value. *W. globosa* stock maintained in Marine Plankton Culture laboratory

from the previous experiment was transferred into each pH medium which was prepared as seven pH values for about 2 weeks. Twenty two fronds cm^{-2} of *W. globosa*, with an average frond size of 0.36 mm^2, were transferred into a tube (r=0.85 cm, h=15 cm). The tube was filled with 10 ml media of each pH medium. Triplicates were applied in each pH media. All experiments were run at temperature of 25 ^{o}C with 12 hours photoperiod and light intensity of 4000 lux.

Frond numbers and frond size of *W. globosa* in each pH media were collected at five days interval for growth determination. Production rate (yield) and relative growth rate (RGR) were collected and calculated by following equation (Guy, Granoth and Gale, 1990).

$$\text{Production rate (Yield, Y)} = (N_2 - N_1) / t$$

$$\text{Relative growth rate (RGR)} = (\ln N_2 - \ln N_1) / t$$

Where N_2 is the final growth (frond number, wet weight or dry weight), N_1 is the initial growth and t is time (hour or day).

All data were analyzed using descriptive statistics and analysis of variance (ANOVA) followed by Duncan's multiple comparison tests. F-values with a probability level < 0.05 were considered as statistical significance.

Effect of initial density on Khai-nam *W. globosa* culture

Initial density of *W. globosa* 0.10, 0.50, 1, 5, 10, 20, 30 and 40% surface area was investigated on performing growth and size effects. Hutner's medium was prepared as same manner in the previous experiment.

W. globosa maintained in Marine Plankton Culture laboratory from the previous experiment was used for the experiment. *W. globosa* frond size about 0.36 mm^2at density of 0.44, 1.32, 2.64, 14.1, 27.75, 55.51, 83.26 and 111.01 fronds cm^{-2} (equal to 0.10, 0.50, 1, 5, 10, 20, 30 and 40% of cultured surface area, respectively) were prepared in tubes (r=0.85 cm, h=15 cm). The tube was filled 10 ml cultured media in temperature of 25 ^{o}C and 12 hours photoperiod at light intensity of 4000 lux. The experiment was run in triplicates.

Fronds numbers and frond size of each treatment were determined every five days. Production rate (yield) and relative growth rate were calculated by following Guy, Granoth and Gale (1990). All data were analyzed using descriptive statistics and analysis of variance (ANOVA) followed by Duncan's multiple comparison tests. F-values with a probability level < 0.05 were considered as statistical significance.

A factorial experiment on light intensity, initial density and pH growth and quality of Khai-nam *W. globosa*

A CRD involved factorial experiment of light intensity, initial pH and initial density to determine an optimal condition for growth and quality of *W. globosa* was investigated. Light intensity of 2,000, 6,000 and 10,000 lux, pH of 5, 6 and 7 and initial density of 5, 10, 15 and 20% surface area (14.10, 27.75, 41.63 and 55.51 fronds m^{-2}, respectively) were selected for the experiment (see detail in Table 3-1.).

Fronds of *W. globosa* maintained in Marine Plankton Culture laboratory with Hutner's medium were evaluated in 3 x 3 x 4 factorial experiment. *W. globosa*, frond size about 0.36 mm^2, were cultured in tubes (r=0.85 cm, h=15 cm). The tube was

filled 10 ml media and all treatments were run in triplicates. All tubes were grown in controlled temperature at 25 ^{o}C with 12 hours photoperiod.

Frond numbers and size of each treatment were counted and measured every seven days for growth determination. Production rate (yield) and relative growth rate were calculated by following Guy, Granoth and Gale (1990). All data was analyzed using descriptive statistics and analysis of variance (ANOVA) followed by Duncan's multiple comparison tests. F-values with a probability level < 0.05 were considered as statistical significance.

OUTDOOR CULTURE SYSTEM OF KHAI-NAM *W. globosa*

Outdoor mass culture of *W. globosa* for growth rate and quality determination was designed in 2 experiments. Firstly, 5 different culture systems to determine production rate of *W. globosa.* Secondly, the culture system yielding the higher production was selected for *W. globosa* quality study.

Mass culture systems were conducted at an agricultural farm, in Mueang District, Sakon Nakhon Province, Thailand.

Five different culture systems; 1) a static culture, 2) a vertical aeration culture, 3) a horizontal movement culture, 4) a system with top water spraying, and 5) a above water layer culturing system with water spraying on the top (see Figure 3-7. for details) were used for mass culture of *W. globosa*.

A static culture had no any circulation during culture period. A vertical aeration culture system, an air stone (400 l hours^{-1} of pressure) was used to circulate the water vertically. A horizontal movement culture, a blade paddle wheel driving by a mini-motor (3,500 rpm) was used to circulate the water horizontally. For top spraying and a layer culturing system with top spraying, water in these 2 systems was moved from the bottom of the culture to the top and sprayed (900 l hours^{-1}) over the surface area. For a layer culture one, a plate of plankton net was placed few centimeters over water surface and water spraying above the net provided. All culture systems were run in black cylinder plastic tanks with an area of 0.152 m^2 with 40 cm high. All cultures were setup in a warehouse which was covered by transparent plastic sheet for protecting rain water.

At culture, 50 liters of Modified Hutner's medium with pH 6 was prepared. Depth of the culture was maintained to 30 cm by adding the freshwater to recover the evaporation. The plastic tank was inoculated with frond density of *W. globosa* as 15% surface area (24 g $tank^{-1}$). The period of this experiment was done in October 2010 to February 2011 under ambient temperature and light conditions.

Environmental parameters such as light intensity, temperature, pH, dissolved oxygen, NO^{-}_{3}-N and PO_4-P (APHA, 1995) of all the outdoor culture systems were monitored every 7 days. Wet weight and frond size of *W. globosa* were investigated after a culture of 28 days. Besides, dry weight was also determined by oven dried at 70 ^{o}C for 24 hours (Driever, Van Nes and Roijackers, 2005).

The five culture systems were run in triplicates. Data were analyzed using descriptive statistics and one way analysis of variance (ANOVA) followed by Duncan's multiple comparison tests. F-values with a probability level < 0.05 were considered as statistical significance

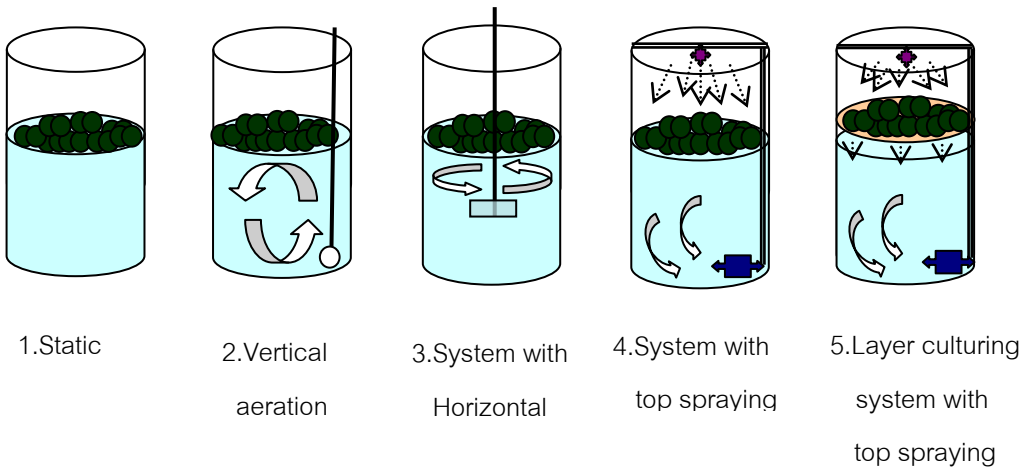

Figure 3-7. Five different culture systems for out door mass production of *W. globosa*

Culture of Khai-nam *W. globosa* for proximate analysis and microbial determination

A system with horizontal flow (Figure 3-7) was used for mass culture of *W. globosa* for proximate analysis and microbial determination. The culture was 28 days in 5 replicates then harvested and dried at 70 ^{o}C for 24 hours. The samples of *W. globosa* were analysis for proximate analysis (AOAC, 2005, 2008), amino acid profile (Petritis, Elfakir and Dreux, 2002) and microbial determination (USFDA/CFSAN/BAM, 2009: online, Chapter 3, 4, 12).

CHAPTER IV

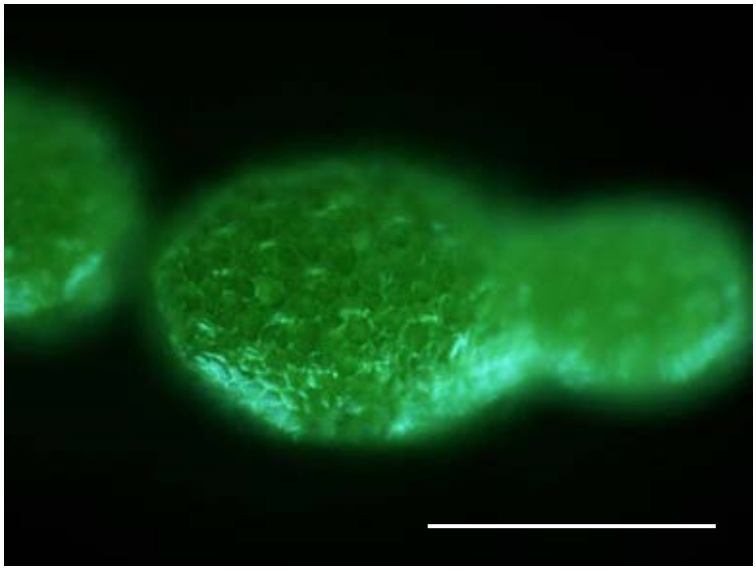
RESULTS

BIOLOGY INVESTIGATION OF KHAI-NAM IN NATURE

Identification of Khai-nam *Wolffia* sp. from the natural pond

Khai-nam collected from a natural pond in Mueang district, Sakon Nakhon province was identified using key of Landolt (1994). The characteristics of Khai-nam were described as stomata number about 16 -18 and the morphology (Figure 4-1) of the fronds was; ellipsoid, with the greatest width distinctly below the surface of the water (all around a translucent edge visible from above), 0.4 – 0.9 mm length, 0.3 – 0.6 mm width, 11/3-12/3 times as long as wide, 3/4 -11/3 as deep as wide, pale green on the surface; cells below the epidermis only slightly smaller than the cells at the bottom of the frond; the lower submerged part of the frond pointing straight down. These characteristics can be described the Khai-nam as *Wolffia globosa*.

a



b

Figure 4-1. a, b *Wolffia* sp. collected at a natural pond in Mueang district, Sakon Nakhon province, Bar = 0.5 mm

Asexual reproduction of Khai-nam *W. globosa*

W. globosa frond was oval shaped with 0.6 mm width, 0.9 mm length. From a single mother frond, a daughter developed in 66 hrs as 4 steps; ¼ of mother frond size, ½ of mother frond size, ¾ of mother frond size and balance with mother frond size. The mother prepared to release the daughter in 6 hours and the mother frond released the daughter frond within 24 hours. Frond of *W. globosa* which collected from natural pond in the northeast of Thailand used 96 hours for a doubling time (Figure 4-2). Environment conditions in the natural pond were 12: 12 hours of light: dark period, 25 – 28 ^{o}C of air temperature, 22 – 26 ^{o}C of water temperature, pH at 6.8 – 7.0, Dissolved Oxygen of 1 – 5 mg l^{-1}, NO_3^-- N of 20 – 25 mg l^{-1} and 10 – 15 mg l^{-1} of PO_4-P.

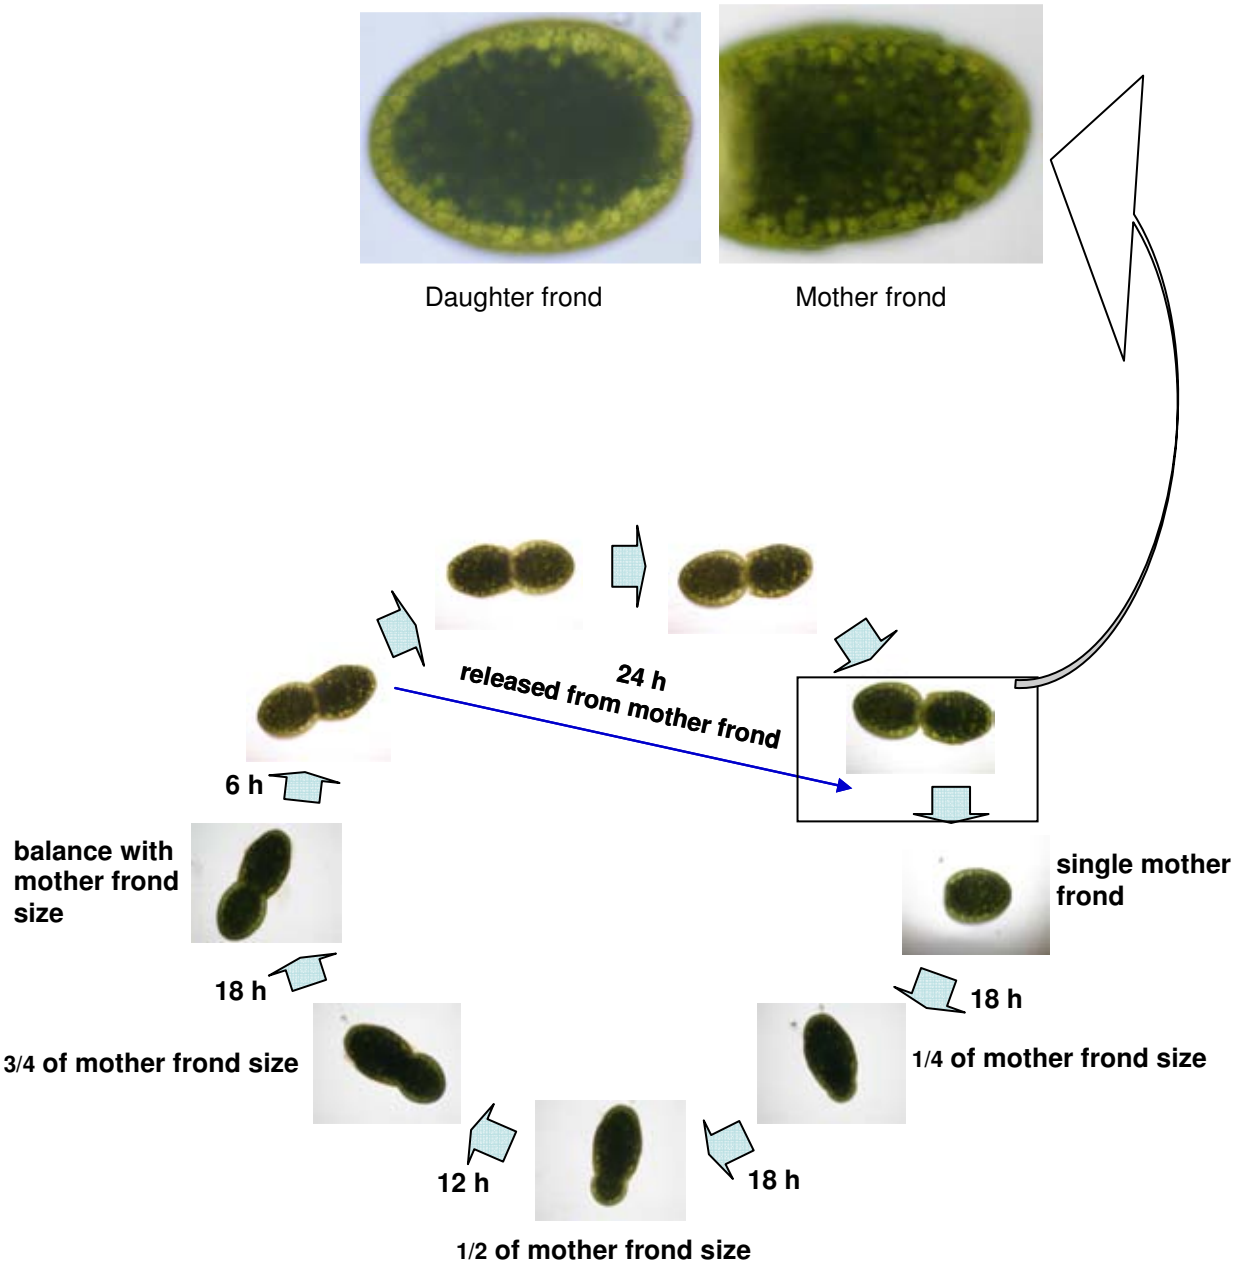


Figure 4-2. Asexual reproduction of *W. globosa*

Production rate of Khai-nam *W. globosa* on natural pond

Production of *W. globosa* was collected at natural pond every month for a year (March, 2008 – February, 2009) period. The result is shown in Figure 4-3. It indicated that production of *W. globosa* was high in June, July and August. The maximal production peak 65.18 g dry weight m^{-2} was found in July. It appeared that *W. globosa* reached their maximal production during the rainy season. During drought season with low temperature in December to February *W. globosa* production declined.

The environment condition in the natural pond during data collecting (March, 2008 – February, 2009) is showed in Table 4-1.

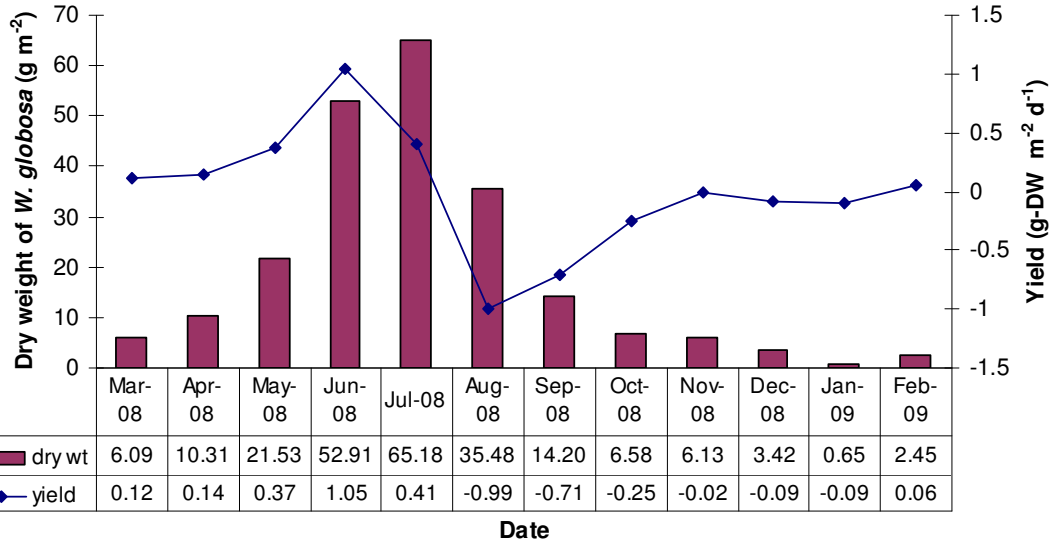

Figure 4-3. Production of *W. globosa* at the natural pond during the year of 2008

Proximate analysis and microbial determination (Table 4-2.)

Proximate analysis of *W. globosa*, collected locally at a small pond in Mueang district, Sakon Nakhon province, was 33.3% protein, 5.0% fat, 10.4% crude fiber. Amino acid profiles indicated that *W. globosa* has fully essential amino acid with high level of cystine. Furthermore, microbial determination showed that *W. globosa* had little contamination of pathogenic bacteria.

FACTORS EFFECTING ON KHAI-NAM *W. globosa* PRODUCTION

Culture media experiment

Statistically significant differences ($p<0.05$) were found among the 5 culture media (Figure 4-4.). Frond of *W. globosa* in natural water 2 had longer life span as 19.07±2.65 days than other media. The life span in other culture media were 17.37±2.9, 15.87±3.81, 14.57±3.0 and 13.95±4.07 days in Hutner's medium, natural water 1, Hoagland's medium and distilled water (control), respectively. There was no significant difference between the life span of the natural water 2 and Hutner's medium.

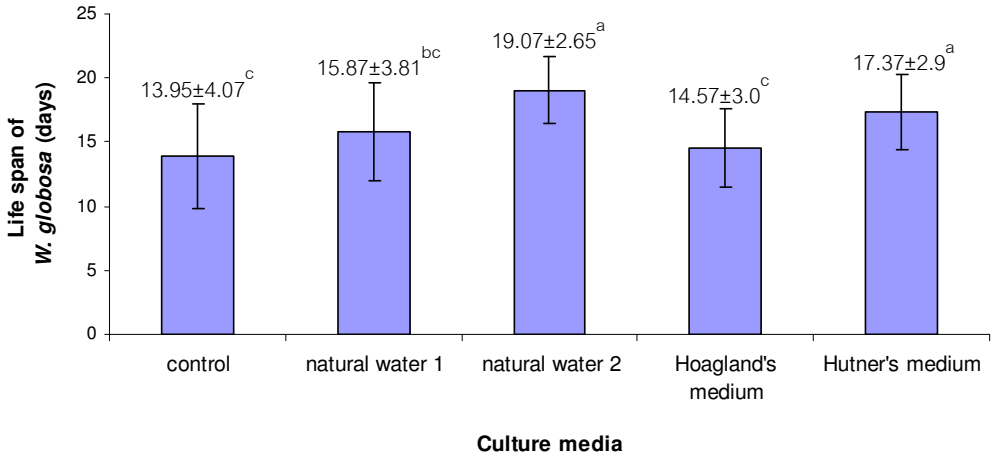

Figure 4-4. Life span of *W. globosa* in 5 different culture media
a, b and c denoted significant difference in mean ($p<0.05$)

The mean number of daughter fronds produced was significantly different among culture media. *W. globosa* in Hutner's medium and control produced the highest number of daughter fronds (mean=6.17±0.96 fronds) and the lowest (mean=2.25±1.25 fronds), respectively (Figure 4-5.). There was no significant difference between the daughter fronds number of Hutner's medium and Hoagland's medium.

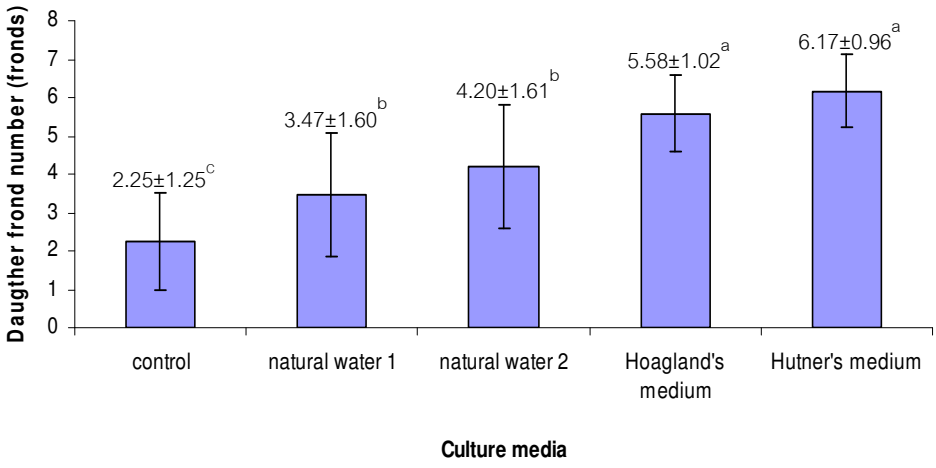

Figure 4-5. Daughter frond (G1) number of *W. globosa* in culture media
a, b and c denoted significant difference in mean ($p<0.05$)

Production rate of *W. globosa* in Hoagland's medium which provided 0.20±0.03 fronds $ml^{-1}d^{-1}$ was significantly higher than other culture media (0.11±0.05, 0.11±0.05 and 0.09±0.05 fronds $ml^{-1}d^{-1}$ in natural water 1, 2 and control, respectively) (Figure 4-6.). However, production rate of *W. globosa* cultured in Hoagland's medium and Hutner's medium (0.18±0.04 fronds $ml^{-1}d^{-1}$) was not significant difference.

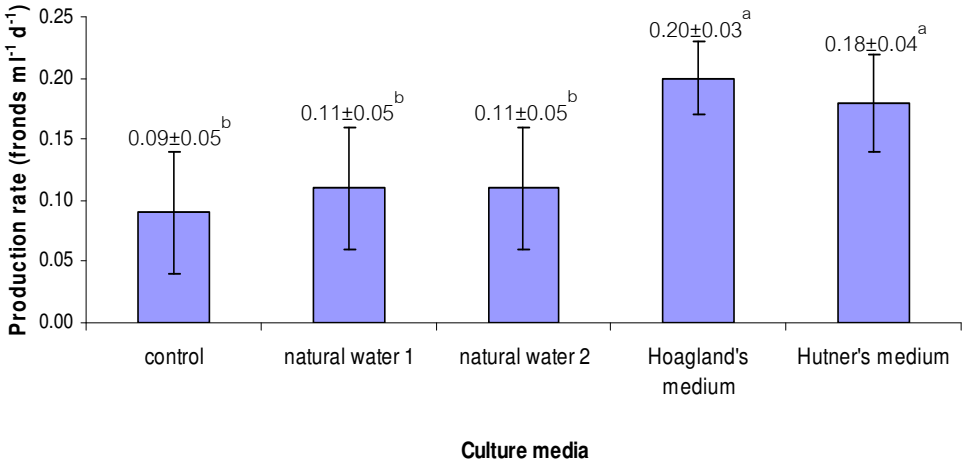

Figure 4-6. Production rate of *W. globosa* in 5 different culture media
a and b denoted significant difference in mean ($p<0.05$)

Division time or doubling time of *W. globosa* in 5 different culture media in Figure 4-7. indicated that the mean division time of *W. globosa* was significantly different ($p<0.05$) among culture media. For first division (G0-G1), fronds of *W. globosa* cultured in Hoagland's medium (3.46±0.55 days) and Hutner's media (3.50±0.61 days), division time was much significantly shorter than in others (6.53±5.60, 6.83±6.30 and 9.60±6.24 days of the natural water 1, natural water 2 and control, respectively). For later division, the results were still as the same sequence of the first division. However, in the third division (G2-G3) *W. globosa* cultured in control and natural water 1 could not occur.

	G0 - G1	G1 - G2	G2 - G3
control	9.60 ± 6.24^{c}	8.25 ± 3.5^{b}	0
natlural w ater 1	6.53 ± 5.60^{b}	6.64 ± 2.66^{b}	0
natural w ater 2	6.83 ± 6.30^{bc}	8.5 ± 7.07^{b}	8 ^{b}
Hoagland's medium	3.46 ± 5^{a}	2.94 ± 0.51^{a}	3.38 ± 0.23^{a}
Hutner's medium	3.50 ± 0.61^{a}	2.84 ± 0.35^{a}	3.19 ± 0.46^{a}

Figure 4-7. Division time in the generation of *W. globosa* on culture media
a, b and c denoted significant difference in mean of column ($p<0.05$)

Frond sizes of *W. globosa* in 5 different culture media were significantly difference ($p<0.05$) (Figure 4-8.). The daughter frond (G1) in Hoagland's medium produced the biggest frond of 0.73±0.06 mm^2 with significant difference from others, except the culture of Hutner's medium. The smallest fronds were found in the control one (non nutrients). In granddaughter frond (G2), the fronds in Hoagland's medium and Hutner's medium had the biggest size 0.57±0.08 mm^2. In G3, the similar result was observed.

	G1	G2	G3
control	0.21 [b]	0.2 [b]	0
natlural w ater 1	0.25 [b]	0.25 [b]	0
natural w ater 2	0.26 [b]	0.25 [b]	0.26 [b]
Hoagland's medium	0.73 ± 0.06[a]	0.57 ± 0.08[a]	0.51 ± 0.04[a]
Hutner's medium	0.72 ± 0.15[a]	0.57 ± 0.07[a]	0.57 ± 0.06[a]

Figure 4-8. Frond size in generation of *W. globosa* in 5 different culture media a and b denoted significant difference in mean of column ($p<0.05$)

The results of culture media effects on life span, daughter frond number, production rate, division time and frond size of *W. globosa,* indicated that Hutner's medium provided a better performance than the other culture media. Therefore, Hutner's medium was selected for the next experiments.

Light intensity effect on photosynthesis of Khai-nam *W. globosa*

Effect of light intensity (natural condition) on photosynthesis of *W. globosa* was investigated under the natural light. The various light intensity and temperature ranged 500 to 100,000 lux and 22 to 35 ^{o}C, respectively (Figure 4-9.) were used to determine effects on chlorophyll fluorescence values; Fv (variable fluorescence) and Fm (maximum fluorescence). The result showed the value of Fv/Fm more than 0.8 (Figure 4-10.). It indicated no effect of day light intensity on photosynthesis of *W. globo*sa in natural condition.

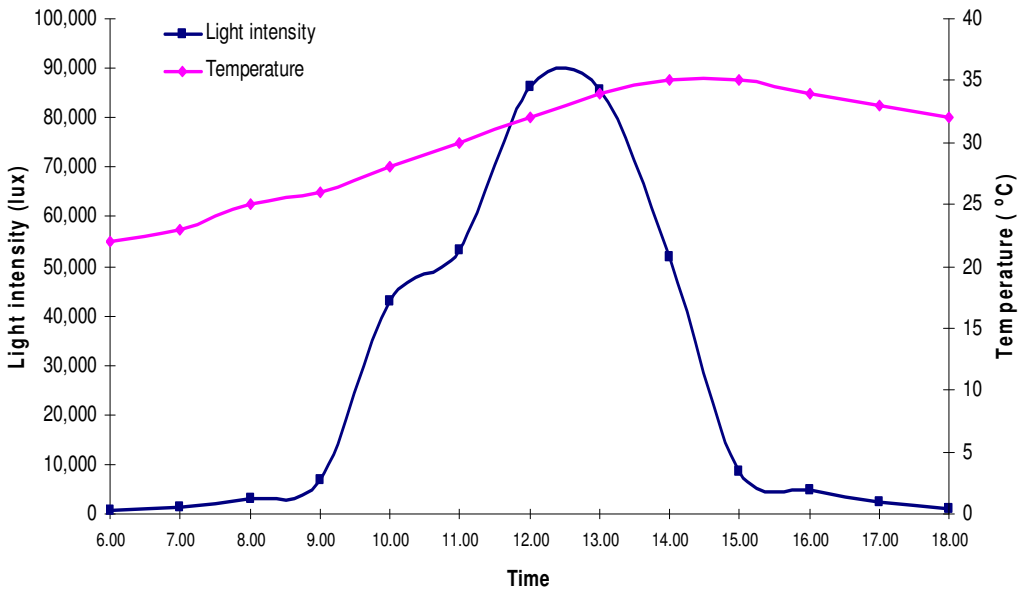

Figure 4-9. Various light intensity and temperature during a day on December 2009

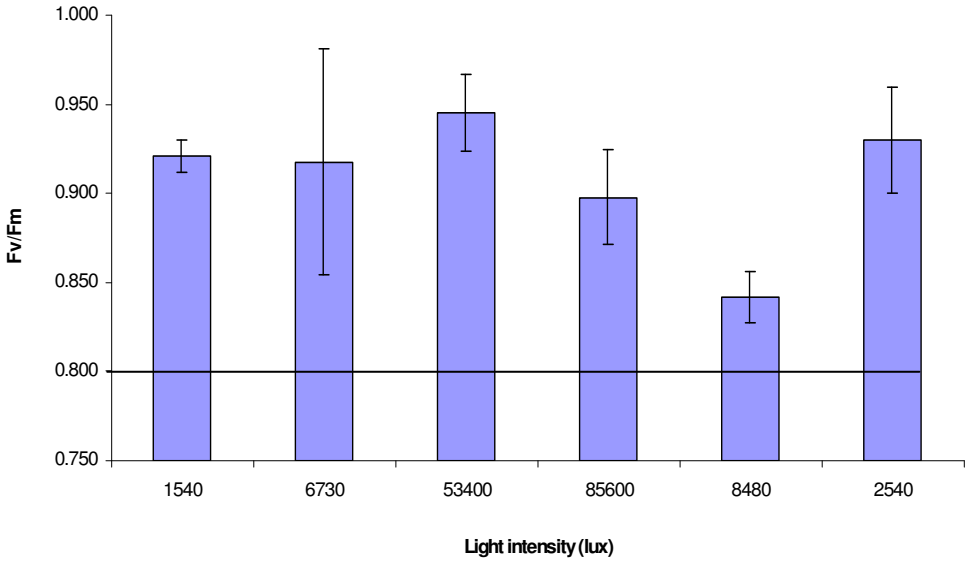

Figure 4-10. Effect of light intensity on photosynthesis efficiency of *W. globosa*

Effect of temperature on photosynthesis on Khai-nam *W. globosa*

Various temperatures ranged 10-40 °C with light intensity 5000 lux was used to determine effects on chlorophyll fluorescence values; Fv (variable fluorescence) and Fm (maximum fluorescence) ratio. The result showed the value of Fv/Fm more than 0.8 under temperatures during 10-35 °C (Figure 4-11.), indicated that temperatures between 10 and 35 °C were no effect on photosynthesis of *W. globosa*. It optimal quantum yield was determined under these temperature. On the contrary, fronds of *W. globosa* in the temperature at 40 °C showed Fv/Fm ratio less than 0.8 (Figure 4-11), indicating that the temperature at 40 °C reduced photosynthesis of *W. globosa*.

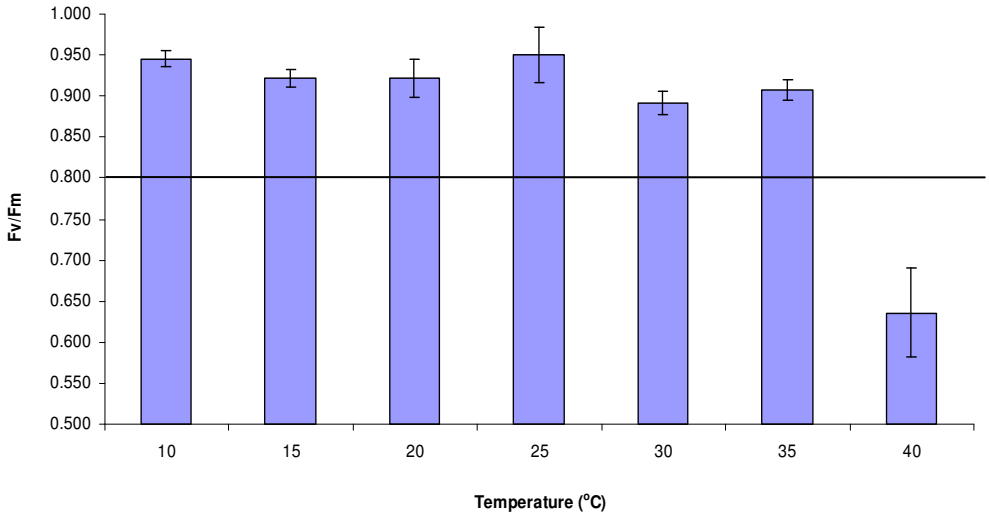

Figure 4-11. Effect of temperature on photosynthesis efficiency of *W. globosa*

Effect of initial pH on performance of growth in Khai-nam *W. globosa*

Frond numbers of *W. globosa* were evaluated in seven initial pH; 4, 5, 6, 7, 8, 9 and 10 with every 5 days observation (Figure 4-12). The results showed that the initial pH at 5, 6 and 7 provided positive frond number throughout the entire period of cultivation and produced higher frond number of 367.0±10.0, 390.7±12.0 and 331.5±10.4 fronds m^{-2}, respectively in 25 days of cultivation. At pH 4 and 10 frond production increased rapidly and then decreased after day 5 until the end of the experiment. The initial pH at 8 and 9 provided little positive frond numbers of 50.4±9.6 and 38.7±6.2 fronds m^{-2}, respectively, at the end of cultivation.

Production rate of *W. globosa* calculated from frond numbers indicated that the initial pH 6 provided the highest yield of 10.3±0.4 fronds $m^{-2}d^{-1}$ significantly difference with others ($p<0.05$), except pH 5 (9.9±0.4 fronds $m^{-2}d^{-1}$) The production for pH 7, 8, 9, 4 and 10 were 9.23±0.4, 0.93±0.3, 0.6±0.2, - 0.7±0.1 and – 0.7 fronds $m^{-2}d^{-1}$, respectively (Figure 4-13).

Frond size of *W. globosa* cultured in initial pH 4 to 10 showed in Figure 4-14, the results showed that frond size at day 10 was bigger than the early or later days. Initial pH 6 provided bigger frond size (0.48±0.12 mm^2) than others. Initial pH 7, 5, 8, 9, 4 and 10 gave frond size of 0.47±0.11, 0.45±0.12, 0.44±0.12, 0.39±0.09, 0.37±0.12 and 0.36±0.10 mm^2, respectively. After 10 days the fronds size of all pH decreased until the end of experiment. The fronds size after 30 days is showed in Figure 4-15. *W. globosa* grew in all pH, frond size decreased dramatically with time of culture.

Effect of initial density on Khai-nam *W. globosa* culture

Frond numbers of *W. globosa* were evaluated in eight initial densities 0.1, 0.5, 1, 5, 10, 20, 30 and 40% of surface area. Growth of *W. globosa* was determined every 5 days and result is showed in Figure 4-16. Production rate of *W. globosa* calculated from frond number indicated that 10% of surface area provided the highest yield of 8.47±0.20 fronds $cm^{-2}d^{-1}$ and significantly difference to other density ($p<0.05$). The productions in 20, 5, 30, 1, 40, 0.5 and 0.1% of surface area were 8.22±0.21, 7.91±0.18, 6.01±0.23, 5.60±0.19, 4.23±0.32, 3.56±0.17 and 1.77±0.18 fronds $m^{-2}d^{-1}$, respectively (Figure 4-17). Relative growth rate (RGR) of *W. globosa* in 0.1% surface area was the highest (0.16 d^{-1}). RGR's 0.15, 0.14, 0.12, 0.12, 0.09, 0.07 and 0.06 d^{-1} were found in 0.5, 1, 5, 10, 20, 30 and 40% of surface area, respectively.

Frond size of *W. globosa* cultured in various initial densities is showed in Figure 4-18. The results showed that frond size in 0.1% surface area was the biggest 0.41±0.03 mm^2 in 25 days of culture. Fronds size of *W. globosa* decreased in 20, 30 and 40% surface area throughout the entire cultivation. The fronds size after 30 days is showed in Figure 4-19. There was significant difference among initial densities, 0,1% of surface area provided the biggest frond size 0.40±0.03 mm^2 and 40% of surface gave the lowest frond size of 0.27±0.02 mm^2.

Factorial experiment on light intensity, initial density and initial pH on the performance of growth and quality of Khai-nam *W. globosa*

3x3x4 completely randomized design involved factorials consisted of light intensity (2,000, 6,000 and 10,000 lux), initial pH (5, 6 and 7) and initial density (5, 10, 15 and 20% surface area) was performed on growth and quality of *W. globosa*. Frond number and size were evaluated. The results showed that frond number of all treatment were increased throughout the entire cultivation 28 days, however, after 21 days-culture the fronds number in most treatment, decreased at the end of experiment, the factor of light intensity 10,000 lux, pH at 6 and 15 % surface area (41.63 fronds cm^{-2}) provided the highest fronds number 442±8 fronds cm^{-2}. The factor of light intensity 2,000 lux, pH at 5 and 5% of surface area (14.10 fronds cm^{-2}) provided the lowest fronds number 59±7 fronds cm^{-2}(Figure 4-20.).

Production rate of *W. globosa* calculated from frond number indicated that the factor of light intensity 10,000 lux, pH at 6 and 15% surface area (41.63 fronds cm^{-2}) provided the highest yield 14.29±0.28 fronds $cm^{-2}d^{-1}$ and relative growth rate of 0.08 d^{-1} was significantly difference to other treatments ($p<0.05$). The factor of light intensity 2,000 lux, pH at 5 and 5% of surface area (14.10 fronds cm^{-2}) provided the lowest yield 1.59±0.24 fronds $cm^{-2}d^{-1}$ with relative growth rate of 0.05 d^{-1}. The factor of light intensity 10,000 lux, pH at 6 and 5% surface area (14.10 fronds cm^{-2}) provided the highest relative growth rate 0.10 d^{-1}. The factor of light intensity 2,000 lux, pH at 5 and 20% of surface area (55.51 fronds cm^{-2}) provided the lowest relative growth rate of 0.03 d^{-1} (Figure 4-21.).

Frond size of *W. globosa* cultured in 3x3x4 factorial experiment is showed in Figure 4-22. The results showed that frond size in the factor of light intensity 2,000 lux, pH at 5 and 5% surface area (14.10 fronds cm^{-2}) provided the biggest 0.38 mm^2 in 14 days – culture. The factor of light intensity 10,000 lux, pH at 6 and 20% of surface area (55.51 fronds cm^{-2}) provided very small frond size of 0.27 mm^2. The fronds size after 28 days-culture is showed in Figure 4-23. The factor of light intensity 2,000 lux, pH at 6 and 5% surface area (14.10 fronds cm^{-2}) provided the biggest 0.34 mm^2 and the factor of light intensity 10,000 lux, pH at 6 and 20% of surface area(55.51 fronds cm^{-2}) provided very small frond size of 0.27 mm^2, nevertheless, there was no significant difference among treatments.

From this experiment, treatment at 31 consists of initial pH at 6 and initial density at 15% surface area was used for the outdoor culture systems.

OUTDOOR CULTURE SYSTEM OF KHAI-NAM *W. globosa*

Culture systems test

Mass culture of *W. globosa* was evaluated in five different culture systems, a static, a vertical aeration, a system with horizontal, a system with top spraying and a layer culturing system with top spraying (Figure 4-24.), throughout the entire period of outdoor cultivation (28 days).

W. globosa was cultivated under the laboratory condition and then transferred to the outdoor in five different culture systems. Growth by wet weight of *W. globosa* determined every 7 days (Figure 4-25.) indicated that a system with horizontal flow provided the highest yield of 1,073.46±54.32 g m^{-2} and significantly difference to others in 28 days ($P<0.05$). The productions in other systems were 877.89±86.67, 783.03±123.36, 726.62±190.32 and 641.14±40.64 g m^{-2} in the system with top spraying, static, vertical aeration and layer culturing system with top spraying, respectively.

Dry weight of *W. globosa* was also evaluated and the result showed that a system with horizontal flow provided the highest yield of 42.94±2.17 g m^{-2} and significantly difference with others in 28 days ($P<0.05$). The productions in other system were 35.123.47±, 31.32±4.93, 29.06±7.61 and 25.65±1.63 g m^{-2} in the system with top spraying, static, vertical aeration and layer culturing system with top spraying, respectively (Figure 4-26.).

A 21 days-culture of *W. globosa* in a system with horizontal flow produced 1.52±0.04 g dry weight $m^{-2}d^{-1}$ which was significantly higher than those in other systems (1.18±0.17, 0.96±0.27, 0.94±0.04 and 0.86±0.09 g dry weight $m^{-2}d^{-1}$ for system with top spraying, vertical aeration, static and layer culturing system with top spraying, respectively) (Figure 4-27.).

Frond size of *W. globosa* in 7 days was 0.59±0.09, 0.53±0.03, 0.49±0.03, 0.48±0.08 and 0.47±0.06 mm^2 in vertical aeration, system with horizontal flow, system with top spraying, layer culturing system with top spraying and static, respectively, however, each culture system was not significantly different (Figure 4-28.).

The environment condition during the outdoor cultivation was showed in Table 4-3. All culture systems had similar values of environment factors.

Culture of Khai-nam *W. globosa* for proximate analysis and microbial determination

W. globosa was cultivated in modified Hutner's medium (1953) at pH 6 with 30 cm depth of tank. The culture was run an outdoor and harvested after 28 days. The proximate analysis and microbial determination form the system with horizontal flow is shown in Table 4-4. It indicated that *W. globosa* contained 48.2% protein, 9.6% fat, 14.5% crude fiber and fully amino acids profile. Furthermore, microbial determination showed a limit number or non pathogen microbial.

CHAPTER V

DISCUSSIONS

INVESTIGATION OF KHAI-NAM BIOLOGY IN NATURAL POND

Khai-nam collected from the natural pond in Mueang district, Sakon Nakhon province, is identified as *Wolffia globosa* because of its morphology and the nucleotide sequence (Sangdee et al., 2010). *Wolffia*, duckweed, is the most reduced plant, its general form and shoot architecture has been difficult to study and interpret (Landolt, 1986, 1998). Systematic studies agree that evolution in the family has proceeded from a more complex to more reduced forms, the physically smallest and simplest genus, *Wolffia,* represents the more derived condition (Daubs, 1965; Den Hartog, 1975; Landolt, 1986; Les, Landolt and Crawford, 1997).

Sangdee et al. (2010) reported that 18 samples of *Wolffia* spp. collected from the north-east of Thailand provided the nucleotide sequence of maturase K and 5' *trnK* intron consist of 431 and 443 bps, respectively. The nucleotide sequences showed highly homology with muturase K and 5' *trnK* of *Wolffia globosa* in GenBank databases, indicated that these 18 *Wolffia* samples are *W. globosa.*

Asexual reproduction of Khai-nam *W. globosa*

The result of frond division time of *W. globosa* in this study is comparable with those found in other studies. One known estimate of the production rate for *W. borealis* was 0.62 fronds per day (Lemon et al., 2001), frond division time of 38.64 hours frond^{-1}, which is much lower than 40.36 hours frond^{-1} reported in this study. The differences between this study and the other may due to environmental conditions and illustrate the phenotypic plasticity of these plants (Landolt, 1986). Other study estimated for the frond division time of *W. arrhiza* was 4 days per frond (Sakdisuwan, 1967), which is similarly reported in this study.

Production rate of Khai-nam *W. globosa* on natural pond

Bhanthumnavin and McGarry (1971) reported that a 9 month period (November - July), productivity of *W. arrhiza* in northern Thailand (the small scale opened pond cultivation used rain water in Chiangmai) was 3.89 g dry weight $m^{-2}d^{-1}$. In addition, duckweeds reproduce by vegetative reproduction and are characterized by rapid clone growth. Yields equivalent in outdoor tanks maximum yields approached 5 g dry weight $m^{-2}d^{-1}$ (Said et al., 1979). Comparing this experiment with 2 reports, low yield (1.05 g dry weight m^{-2} d^{-1}) in the natural pond at Mueang district, Sakon Nakhon province is found. The various production rates as reported in varies considerably due to species, age of the plant, nutrients and other environment conditions.

Proximate analysis and microbial determination

The comparison protein, fat, crude fiber content and essential amino acid profile of the protein concentrate between *W. globosa* in this experiment and *W. arrhiza* (Jairakphan, 1999) (Table 5-1.). The result showed that *W. globosa* collected from the natural pond provided higher protein content and fat content of 33.3% and 5.0%, respectively, than *W. arrhiza* which was collected from natural pond, however, crude fiber content in *W. arrhiza* was produced higher than another one.

Trytophan, the essential amino acid profile of the protein concentrate in *W. arrhiza* was provided higher than *W. globosa.*

The result of this comparison was similar the previous reports. The crude protein content of *Wolffia* obtained from natural waters (ponds, lakes, ditches, streams and paddy fields) has been reported to range from 7 to 20% (Tan, 1970; Bhanthumnavin and McGarry, 1971; Jairakphan, 1999). Grown in enriched waters containing mineral media or effluents from agricultural and municipal waste lagoons, the protein content (30 – 45 %) was greatly increased over that from natural waters with low nutrients (Rusoff et al., 1980; Fujita et al., 1999; Chantiratikul et al., 2010). However, *W. globosa* collected the natural pond provided high protein, fat, crude fiber content and essential amino acid profile of the protein concentrate.

Table 5-1. Proximate analysis of *W. arrhiza* and *W. globosa* (dry matter)

Components	*Wolffia arrhiza* (Jairakphan, 1999)	*Wolffia globosa* (Natural pond in this study)

FACTORS EFFECTING ON KHAI-NAM *W. globosa* PRODUCTION

Culture media experiment

Five different culture media were compared on life span, daughter frond number, production rate, division time and frond size of *W. globosa*. The results found that Hoagland's medium provided shorter life span of *W. globosa* than that of the others, but yield of *W. globosa* cultured in Hoagland's and Hutner's media was higher (0.40 and 0.36 fronds d^{-1}, respectively) comparing to others. On the contrary, the natural water pond 2 had longer life span of 19.07 days than that of others, but the yield was the lowest as the control one. Moreover, daughter frond number in Hutner's medium gave the highest of 6.17 fronds throughout life span of mother frond. Lemon et al. (2001) reported that *W. borealis* grown in 33% v/v strength Hutner's medium, adjusted to pH 6.5, provided life span 15.8 days, daughter frond 9.8 fronds and production rate 0.62 fronds d^{-1}, which are similar life span of *W. globosa* in this study. Life span of *W. globosa* in this study (17.37 days) is longer than the 1.57 days of *W. borealis*, but daughter frond number of *W. borealis* is more than the 3.63 fronds of *W. globosa*. Moreover, production rate of *W. borealis* is more than the 0.26 fronds d^{-1} of *W. globosa*. The differences may due to environmental conditions and illustrate the phenotypic plasticity of the plants (Landolt, 1986).

Bernard et al. (1990) studied flower structure, anatomy and life history of *W. australiana* reported that life span was 17 days and 11 fronds were produced. Frond size at detachment decreased with increased age of plant, which is similarity the present experiment as size decrease with increasing generation of *W. globosa.*

Hillman (1961) reported that most duckweed grew better in 1/3 strength Hutner's medium, but in dilution of 1/100 reduced growth in many species. In general, *Wolffia* L. *trisulca* or those with thin fronds grew better than others on dilute media (Landolt, 1957)

Effect of light intensity on photosynthesis effecting of Khai-nam *W. globosa*

The Fv/Fm testing is used the primary method for checking and choosing factors which is relative the photosynthesis such as light intensity and temperature. Fv/Fm is a dark adapted test used to determine maximum quantum yield. This ratio is an estimate of the maximum portion of absorbed quanta used in PSII reaction centers. It is import to property dark adapt samples for this test. Fo will be raise and Fm will be lowered if dark adaptation is inadequate. Since dark adaptation requirement can vary with species, varieties, mutants and sun vs. shade leaves testing should be done to ensure proper dark adaptation (Kitajima and Butler, 1975). The present experiment used the same basic information for examining. In 2009, December is winter season in Thailand thus this data will be representation in winter season. Temperature of water surface was between 22 and 35 ^{o}C and light intensity of was between 500 and 100,000 lux (about 9.25 to 1,850 μE $m^{-2}s^{-1}$) are no effect on photosynthesis of *W. globosa.*

Effect of temperature on photosynthesis effecting Khai-nam *W. globosa*

The Fv/Fm testing is used as primary method for checking and choosing factors which is relative the photosynthesis such as light intensity and temperature**.** Fv/Fm is a dark adapted test used to determine maximum quantum yield and Fv/Fm take only a second to make a measurement. In this experiment, temperature at 40 ^{o}C had effect on photosynthesis of *W. globosa*. Wedge and Burris (1982) studied effects of light and

temperature on duckweed photosynthesis and reported that duckweeds had a temperature optimum between 30 and 35 ^{o}C. Plants show decreasing photosynthesis only when the temperature exceeds 40 ^{o}C (Hew, Krotkov and Canvin, 1969).

Effect of initial pH on performance of growth in Khai-nam *W. globosa*

Effect of pH on growth of *W. globosa* is clearly indicated that initial pH at 4, 8, 9 and 10 had no suitability for culturing *Wolffia.* Initial pH at 5, 6 and 7 are suitable for culturing *W. globosa*. *Wolffia* has an optimum growth at pH 5 and growth declined with increasing pH (McLay, 1976) In natural ponds, the pH at 6.5 to 7.0 of the water was an optimized pH (Bhanthumnavin and McGarry, 1971). In controlled laboratory condition, pH at 5 to 6 was suitable pH for the optimal growth of *Wolffia* (Rowchi and Somboon, 2007). Hillman (1961) reported that *Lemna* and *Wolffia* grew well in pH at 4.5 to 7.5 and outer limits at 3.5 and 8.5, moreover, there may be small differences in the pH tolerance of various species.

Effect of initial density on Khai-nam *W. globosa* culture

This experiment indicated that relative growth rate (RGR) and frond size of *W. globosa* decreased with increase of initial density. It is similar the other researchers found. Driever et al. (2005) suggested that crowding was an important factor in limitation of duckweed growth. Growth rates of duckweed is produced decreasing with increasing density, moreover, it could well be described as growth limitation by biomass. Suppadit et al. (2008) reported that the initial biomass level of 4 g l^{-1} yielded the highest increase in biomass, whereas the initial biomass level of 16 g l^{-1} provided the greatest decrease in biomass, this might be because of the low survival of *W. arrhiza*.

A factorial experiment on light intensity, initial density and initial pH on the performance of growth and quality of Khai-nam *W. globosa*

Effect of light intensity, initial pH and initial density using 3x3x4 factorial design consist of light intensity at 2,000, 6,000 and 10,000 lux, initial pH at 5, 6 and 7 and initial density at 5, 10, 15 and 20% surface area, on growth of *W. globosa* was evaluated. This result indicated high light intensity (6,000 and 10,000 lux) is suitability for *Wolffia* cultivation. It is similar the other study, Hillman (1961) reported that the effect of light duration and intensity appear to be relatively uncomplicated. Light intensities below about 7,000 lux, the multiplication rate of studied duckweed increases with increasing daily duration of expire, reaching a maximum under continuous light (Clark, 1925; Landolt, 1957).

Landolt (1957) reported that fluorescent was used as light supplemented to supply various photoperiods and intensities on a large number of lemnaceae. Multiplication rate increased with intensity until a maximal value was reached.

Light intensity provided very high effect on the growth of *W. globosa*, moreover, it has the effect with other factor such as pH and density (Figure 4-21.). The effect of initial pH and initial density depend on light intensity. When high light intensity (6,000 and 10,000 lux), the various of initial pH and initial density are showed the difference distinct on the production rate and relative growth rate (RGR). However, in low light intensity (2,000 lux) is not found the difference between the initial pH and density.

OUTDOOR CULTURE SYSTEM OF KHAI-NAM *W. globosa*

Culture systems test

The present study, the system with horizontal flow produced higher wet weight and dry weight than other systems in 28 days (1073.46 and 42.94 g m^{-2}, respectively). Moreover, the system with horizontal flow produced higher production rate than other one in 21 days- culture (1.52 g-DW $m^{-2}d^{-1}$). This might be because of too dense and some of *W. globosa* died after the 21 days- culture. This is similar to trend that was reported by Suppadit et al. (2008), Suppadit (2011) and Cheng and Stomp (2009).

Production rate in the vertical aeration system was not significantly different throughout 28 days of culture. This might be because of vertical movement interfering normal living of *W. globosa*, since this plant always floats only on the water surface. When it is follow water circulation as verticality. It provide low yield. In 28 days-culture, *W. globosa* in the vertical aeration system produce production rate lower than the static water culture.

For the layer culturing system with top spraying, this culture system provide the lowest yield (wet weight, dry weight and production rate) throughout cultivation, indicated that a layer culturing system with top spraying is unsuitable for mass culture of *W. globosa.* This might be because of frond of *W. globosa* pile up very much on the layer (Figure 4-24.), it is not spread by the water. Therefore, frond surface of *W. globosa* is low the photosynthesis effecting low yield.

Fedler and Duan (2011) studied biomass production for bioenergy using recycled wastewater in a natural waste treatment system and reported the biomass

production of duckweed (containing both *Lemna* and *Wolffia*) in the tank with a TN concentration of about 2 mg l^{-1}. The water surface area was 2.54 m^2 (a radius of 0.9 mm and a height of 0.9 m). The average daily growth rates of duckweed was 99 – 127 g wet weight $m^{-2}d^{-1}$. The mean long –term extrapolated yield of *Lemna* and mixed *Lemna – Wolffia* was 0.003 g dry weight m^{-2} d^{-1} (Edwards et al., 1992). Maximum yield of duckweed was 15 g dry weight m^{-2} d^{-1} using domestic sewage (Oron et al., 1984, 1988; Gaigher and Short, 1986). Nasker et al. (1986) reported a dry weight yield of *W. arrhiza* grown in different concentrations of sewage, ranging from 0.002 to 0.003 g $m^{-2}d^{-1}$. For yield of *Wolffia* in this experiment all 5 different culture system provide 0.51 to 1.90 g dry weight m^{-2} d^{-1}.

Culture of Khai-nam *W. globosa* for proximate analysis and microbial determination

The comparison protein, fat, crude fiber content and essential amino acid profile of *W. globosa* were compared to *W. arrhiza* (Jairakphan, 1999) and *W. columbiana* (Rusoff et al., 1980) as showed in Table 5-2. The result revealed that *W. globosa* grown in a system with Hutner's medium provided higher protein and fat content of 48.2% and 9.6%, respectively, than those of *W. Columbiana* collected from anaerobic dairy waste lagoons on the LSU campus, the lagoons contained from 20 to 40 mg l^{-1} of TKN during the collection period. *W. arrhiza* and *W. globosa* which was collected from natural pond, however, crude fiber content in *W. arrhiza* was produced higher than other one.

The essential amino acid profile of the protein concentrate in *W. columbiana* was provided higher than *W. arrhiza* and *W. globosa.* On the contrary, cystine and tryptophan were found in only *W. arrhiza* and *W. globosa*.

W. globosa grown in culture system was produced protein, fat, crude fiber content and essential amino acid profile of the protein concentrate higher than *W. globosa* grown in the natural pond (except Cystine) and *W. arrhiza* collected from natural pond (except Tryptophan).

The result of this comparison was similar the previous reports. The crude protein content of *Wolffia* obtained from natural waters (ponds, lakes, ditches, streams and paddy fields) has been reported to range from 7 to 20% (Tan, 1970; Bhanthumnavin and McGarry, 1971; Jairakphan, 1999). Grown in enriched waters containing mineral media or effluents from agricultural and municipal waste lagoons, the protein content (30 – 45 %) was greatly increased over that from natural waters with low nutrients (Rusoff et al., 1980; Fujita et al., 1999; Chantiratikul et al., 2010).

Table 5-2. Proximate analysis of *Wolffia* (dry matter)

Component	*Wolffia columbiana* (Rusoff et al., 1980)	*Wolffia arrhiza* (Jairakphan, 1999)	*Wolffia globosa* (in this study)	
			Culture system	Natural pond
Protein (%)	44.7	20.15	48.2	33.3
Fat (%)	6.6	2.43	9.6	5.0

CHAPTER VI

CONCLUSION AND RECOMMENDATION

1. Khai-nam, watermeal, was collected from the local natural pond in Mueang district, Sakon Nakhon province is identified as *Wolffia globosa*.
2. Asexual reproduction of *W. globosa* in the natural pond water needs a complete cycle for 96 hours or 4 days.
3. Production rate of *W. globosa* on natural pond from Sakon Nakhon province provided high growth of 65.18 g dry weight m^{-2} on July and the lowest was 2.45 g dry weight m^{-2}on February. However, June and August provided the highest yield 1.05 g dry weight $m^{-2}d^{-1}$and the lowest yield -0.99 g dry weight $m^{-2}d^{-1}$, respectively.
4. *W. globosa* collected locally at a small pond in Mueang district, Sakon Nakhon province produce 33.3% protein, 5.0% fat, 10.4% crude fiber and fully amino acid and it does not find or a little find the pathogen microbial.
5. Hutner's medium is suitable for *W. globosa* culture.
6. Light intensity under the natural light is not effect on photosynthesis of *W. globosa.*
7. Temperature at 40 ^{o}C has an negative effect on photosynthesis of *W. globosa.*
8. The pH at 5 to 7 of medium can produce high yield of *W. globosa.*
9. Initial density for *W. globosa* cultivation is 5 to 20 % surface area.

10. A factorial experiment on light intensity, initial pH and initial density on the performance of growth and quality of *W. globosa* indicate that the light intensity at 10,000 lux, initial pH at 6 and 15% surface area of initial density produce high yield.
11. The system with horizontal movement in outdoor, *W. globosa* show high yield and it can produce 48.2% protein, 9.6% fat, 14.5% crude fiber and fully amino acids.

RECOMMENDATION

Previous study conduct mass product from different sewage, nutrient resource and record base data about effecting factors, a culture system for *Wolffia* or duckweed has received little attention. I think that the culture system of *Wolffia* should develop for the highest yield.

BIOGRAPHY

Mrs. Nisachol Ruekaewma was born on August 10, 1970 in Sakon Nakhon province. She graduated with the a Bachelor's degree in Fisheries from Fisheries Program, Faculty of Bangphra Agricultural , Rajamangala University of Technology, Chonburi province and graduated with the Master's degree Program in Biotechnology, Faculty of Science, Chulalongkorn Universty, in 1997.

After graduating from Chulalongkorn University she has worked as Rajamangla University of Technology Isan Sakon Nakhon Campus to present.

In 2007, she is a graduate candidate in the Doctoral Degree Program in Biotechnology, Faculty of Science, Chulalongkorn Universty.

Research Publication

Rukeawma, N., S. Piyatiratitivorakul and S. Powtongsook. 2009. Effect of nutrition on vegetative reproduction of Watermeal (*Wolffia* spp.) collected from Sakon-Nakhon province, Thailand. Proceeding of the 35th Congress on Science and Technology of Thailand, October 15-17, 2009, Burapha University.

Ruekaewma, N., S. Piyatiratitivorakul and S. Powtongsook. 2011. Culture system for Khai-nam *Wolffia* sp. for hygiene human food. Proceeding of the 9th Asian Fisheries and Aquaculture Forum, April 21-25, 2011, Shanghai, China.
