CHAPTER IV

RESULTS AND DISCUSSION

4.1. Preliminary screening of glutamate decarboxylase, amylase, and proteinase producing isolates. Totally 116 strains of LAB isolated from various sources were investigated for GABA production, starch and/or casein hydrolyzing abilities. 23 isolates with abilities of interest were selected for further characterized. The list of screened isolates is showed in Table 4.1.General characteristics of selected isolates are shown in Table 4.2.

Table 4.1. LAB isolates: their abilities and source of isolate

Strain	Cell[a]	GABA production	Amylase by starch plate	Proteinase by casein plate	Source (local name)
L13	R	+++	-	+	Japanese pickle (Senmaizukae)
LSF 8-12	R	++	-	++	Fermented fish (Pla-som)
LSF 8-13	R	++	-	++	Fermented fish (Pla-som)
P 46-1	R	+	-	+	Pickle (Pak-sian-dorng)
FS 73-1	R	+	-	-	Fermented fish (Pla-ra), Ubonrajthanii
SR 11-2	R	+	-	-	Soy sauce
SEA 62-2	R	+	-	-	Pine apple
SEA 85-1	R	+	-	-	Sugar cane, Ubonrajthanii
SEA 104-1	R	+	-	-	Rambutan
SEA 138-1	R	+	-	-	Cantaloupe
SG 1-1	C	w	-	-	Grape, Nakornpratom
SG 1-2	C	w	-	-	Grape, Nakornpratom
SG 1-3	C	w	-	-	Grape, Nakornpratom
SB 2-3	R	-	+++	-	Raw Strach, Songkla
U 3-1	R	-	++	-	Fermented starch
N 2-1A	C	-	+	-	Fermented starch
N 12-9	C	-	+	-	Rice (Khao-chae), Nakornrajsrima
FP 15-1	C	-	w	-	Fermented tea leaves (Miang), Chaingmai
933	C	-	w	-	Fermented beef sausage (Mum)
378-1	C	-	w	-	Fermented starch
SCR 1P	R	-	-	++	Red frog crab
SCC 1	C	-	-	++	Red frog crab
SMC 1	C	-	-	+++	Dog feces

+, Positive (number of + corresponded to level of activity); −, negative; w: weakly positive.

[a] Cell morphology: R, rod; C, cocci.

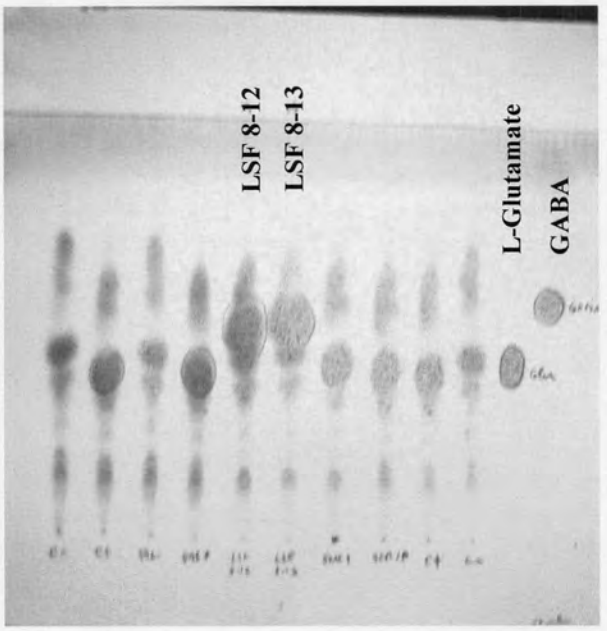

Fig. 4.1. Screening of GABA producing strains by TLC

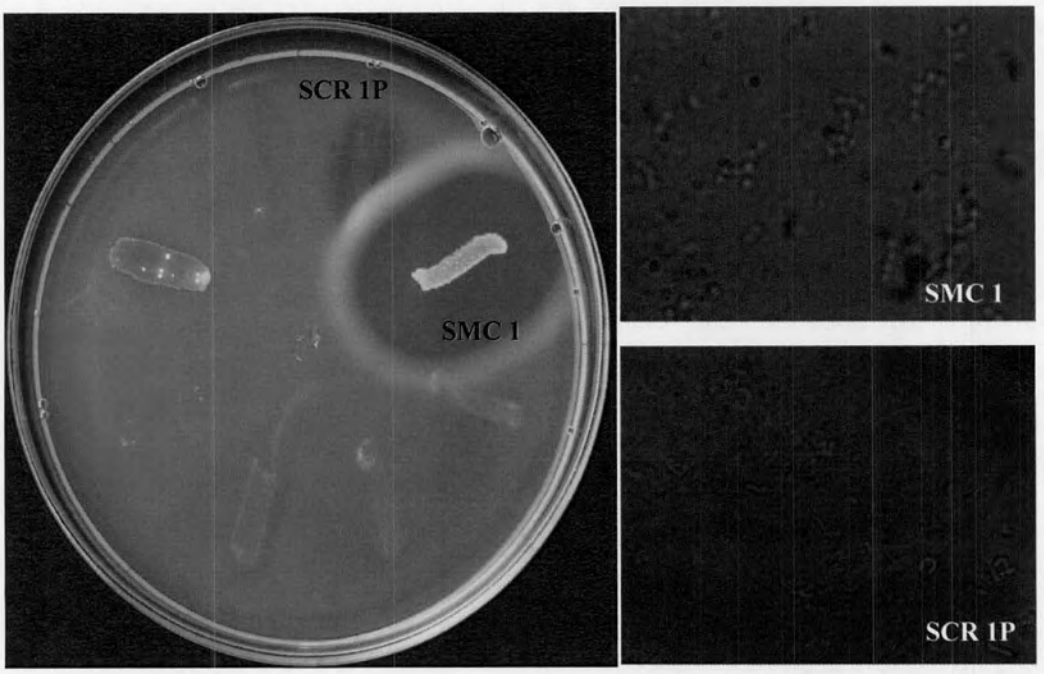

Fig. 4.2. Screening of proteinase producing strain by casein agar plate

TLC plate analysis for GABA producing LAB were done by spotting culture brorth of isolates then GABA detected by ninhydrin solution (Ueno et al., 1997). Strain LSF 8-12 and LSF 8-13 shown GAD activity (Fig. 4.1). Casein hydrolyzing isolates SMC 1 and SCR 1P photos and activity on casein plate are shown (Fig.4.2).

4.2. Identification of the isolated strains

4.2.1 Glutamate decarboxylase producing strains

4.2.1.1 The novel high GABA producing isolate of *Lactobacillus* sp. nov. L13 from Japanese pickle

The strain L13 was isolated from *Senmaizuke,* a Japanese traditional pickle after cultivation on GYP agar plate at 30℃ for 5 days. Single colonies were grown anaerobically in GYP liquid medium containing 5% sodium glutamate at 30℃ for 48 h, then the culture supernatant of each isolate was analyzed for production of GABA by thin layer chromatography (Ueno *et al.*, 2007). The cells were Gram-positive, catalase-negative, non-motile, nonspore- forming short rods (1.0-5.0 x 0.5-0.8 μm, Fig. 4.3). Colonies on GYP agar appear white and circular with a smooth surface and edges (1.0-2.0 mm in diameter after 2 days of growth). Strain L13 growth at 15°C but not at 45 °C. The strain L13 was able to grow up to 8.0 % NaCl; the specific growth rate at 5.0% NaCl is 50% (100% without NaCl). Facultative anaerobic and produced DL-lactic acid heterofermentatively from glucose (5.7% L-lactate and 0.7 % D-lactate). HPLC analysis revealed that it also produced 3% ethanol as other metabolite. L13 produced acid from D-xylose, D-ribose, D-galactose, D-fructose, gluconate, 2-keto gluconate, and *N*-acetylglucosamine. L13 was negative for acid production from glycerol, erythritol, arabinose, L-xylose, adonitol, β-methyl-D-xyloside, D-mannose, L-sorbose, L-rhamnose, dulcitol, inositol, D-mannitol, sorbitol, alpha-methyl-D-mannoside, alpha-methyl-D-glucoside, D-amygdalin, arbutin, salicin, cellobiose, maltose, lactose, melibiose, sucrose, trehalose, inulin, melezitose, raffinose, starch, glycogen, xylitol, gentiobiose, D-turanose, D-lyxose, D-tagatose, D-fructose, L-fructose, arabitol, and 5-keto gluconate. Ammonia is not produced from arginine. Peptidoglycan structure was A4a L-Lys–D-Asp type and the DNA G + C content is 46 mol%.

The 16S rRNA gene sequence (1,443 bp) of the strain L13 was determined and indicated that the strain showed 98% identity to *Lactobacilllus parabrevis* and *Lactobacillus hammesii.* In a neighbour-joining dendrogram (Fig. 4.4 a) based on 16S rRNA gene sequences obtained from this study and from the GenBank database, the strain L13 clearly belonged to the genus *Lactobacillus*, and were positioned very close to *Lactobacillus parabrevis*, which was isolated from wheat and deposited in the ATCC as *L. brevis* (Spiller, 1987), and recently it was reclassified as *L. parebrevis* sp.

nov. (ATCC 53295^T; Vancanneyt *et al.*,2006). *rpoA* gene (527 bp) sequences were determined and analyzed (Fig. 4.4 b). The position of the strain L13 clearly separated from *Lactobacillus parabrevis*. DNA sequence similarity matrixes of 16S rDNA and *rpoA* gene were shown in appendixIII. *rpoA* gene shown high discrimination power that of 16S rDNA. that DNA–DNA hybridization analysis was performed including the most closely related strain based on 16S rRNA gene sequence analysis. DNA–DNA relatedness values of L13 to *Lactobacillus parabrevis* sp. nov. ATCC 53295^T was below 16%. This value is below the threshold of 70% suggested for species delineation (Stackebrandt & Goebel, 1994), indicating that strain L13 represents a separate genomic species.

Based on physiological, biochemical analyses, DNA G + C content and DNA–DNA hybridization of the genomic DNA as shown in Table 4.3 indicated that the strain L13 represent a novel species of the genus *Lactobacillus*.

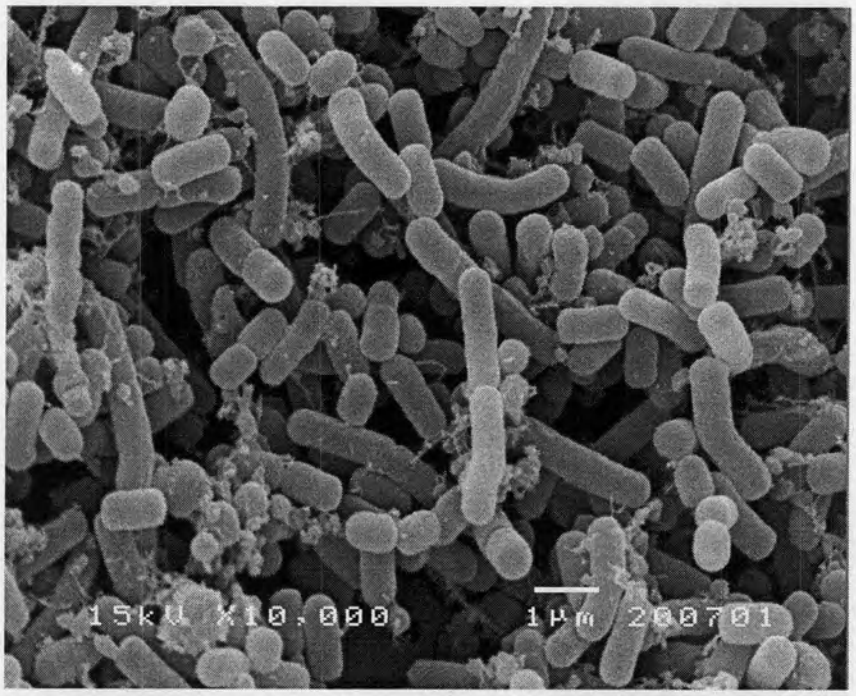

Fig. 4.3. Scanning electron micrograph of L13 grown on GYP agar plate at 30 °C . Bar, 1μm

Table 4.3. Differential characteristics of strain L13 and closely related *Lactobacillus* species. Strains: 1, L13^T; 2, *L. parabrevis* ATCC 53295^T (Data from Vancanneyt *et al.*, 2006); 3, *L. hammesii* CIP 108387^T (Data from Valcheva *et al.*, 2005).

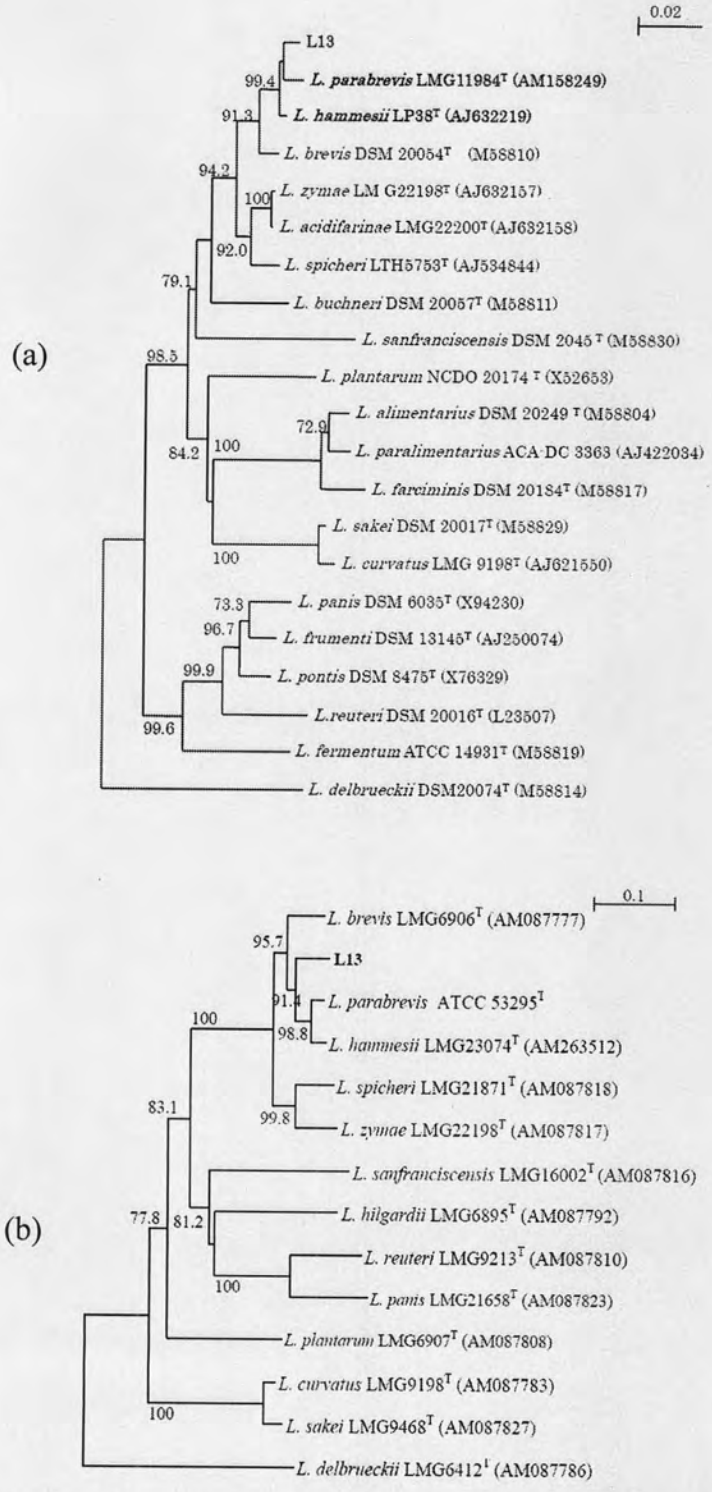

Fig. 4.4. Phylogenetic tree derived from sequence analysis of 16S rRNA gene (a) and *rpoA* gene (b) shown the position of *Lactobacillus sp. nov.* L13 among selected lactobacilli. The tree was generated by the neighbor-joining method. Bootstrap values based on 1000 replications are given at nodes. Bar (a) 2 substitutions and (b) 2 substitutions per 100 nucleotide positions.

4.2.1.2 GABA producing isolates *L. brevis* LSF 8-13, *L. plantarum* SR 11-2, SEA 62-2, and FS 73-1

The selected GABA producing isolates *L. brevis* LSF 8-13, *L. plantarum* SR11-2, SEA 62-2, and FS 73-1 were characterized as previously shown in Table 4.1. 16S rRNA genes were amplified and analyzed as shown in Fig. 4.5.

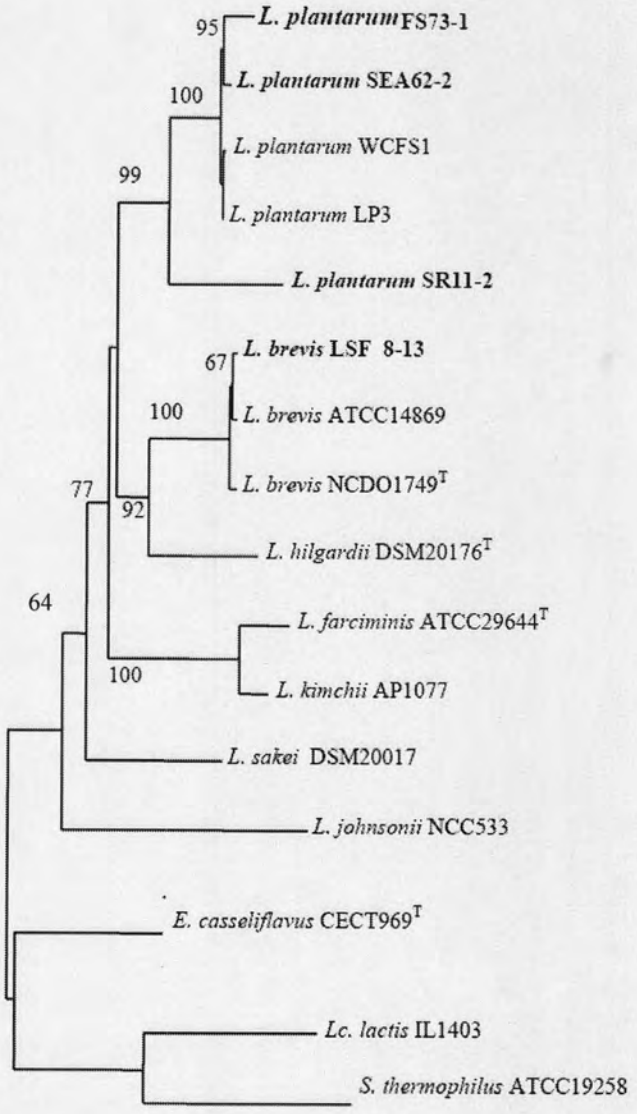

Fig. 4.5. Phylogenetic tree derived from 16S rRNA gene sequence analysis showing the position of selected GABA producing isolates *L. brevis* LSF 8-13, *L. plantarum* SR 11-2, SEA 62-2, and FS 73-1 among selected lactobacilli. The tree was generated by the neighbor-joining method. Bootstrap values based on 1000 replications are given at nodes. Bar, 2 substitutions per 100 nucleotide positions.

4.2.2 Amylase producing strains

4.2.2.1 The novel isolate of *Enterococcus camelliae* sp. nov. FP15-1^T, isolated from fermented tea leaves in Thailand

The FP15-1 was isolated from *Miang*, a fermented tea leaves. Cells were Gram-positive, non-motile, non-spore-forming cocci which arranged in pairs and in chains. Cells were spherical or ovoid, 0.5-1 μm in diameter. Colonies on GYP agar plate were circular, raise or low convex with entire margins and nonpigmented. The strain did not hydrolyze arginine, shown slightly hemolysis on horse blood agar and unable to grow in litmus milk medium. Growth occurred at pH 5.0 to 9.6 and at 15°C to 45°C, and in 2 to 6% NaCl. The strain was negative for catalase, hydrolysis of gelatin, reduction of nitrate, production of gas from glucose, facultatively anaerobic and produced glucose fermentatively. Acid was produced aerobically from D-glucose, D-fructose, D-Cellobiose, esculin, D-mannose, and D-ribose but failed to produced acid from D-amygdalin, L-arabinose, D-galactose, gluconate, glycerol, lactose, D-melibiose, D-melezitose, D-sorbitol, D-xylose, α-methyglucoside, raffinose, L-rhamnose, and inulin. Riboflavin, niacin and calcium-pantothenate were required for growth. DMK-7 was the major menaquinone. Straight-chain fatty acid of $C_{18:1}$ was a dominant composition. The DNA G+C content of type strain is 37.8 mol%.

The almost complete 16S rDNA gene sequence (1490 bp) of FP 15-1^T had the highest similarity to 16S rRNA gene sequence of enterococci. Pairwise sequence alignments indicated that the closest relatives of strain FP 15-1^T were *Enterococcus italicus* (99.2%), *Enterococcus saccharolyticus* (98.3%), *Enterococcus sulfureus* (98.1%) and *Enterococcus casseliflavus* (97.0%). Lower sequence similarities (<97%) were found with other described species of the genus *Enterococcus.* The 16S rRNA gene and *rpoA* gene based phylogenetic tree of strain FP 15-1^T with other enterococci are shown in Fig. 4.6 and 4.7, respectively. Both trees clearly revealed distinct position of the representative strain FP 15-1^T from the nearest neighbor *E. italicus.* The *rpoA* gene sequence of the strain FP15-1^T showed 93.8, 88.3 and 88.1% similar to *E. italicus*, *E. sulfureus* and *E. saccharolyticus*, respectively. Therefore, *rpoA* gene confirmed that the strain FP 15-1 is a separate species with more discriminatory than 16S rRNA. DNA sequence similarity matrixes of 16S rDNA and *rpoA* gene were shown in appendixIII. Hybridization level of 21.6% was found between the type strain of *E. italicus* and the strain FP 15-1^T; this clearly indicated and confirmed that the strain FP15-1^T should be proposed as a novel species of the genus

Enterococcus. The characteristics differentiating the novel species from its other closest enterococci are shown in Table 4.4

Therefore, this strain represent a novel species of the genus *Enterococcus,* for which the name *Enterococcus camelliae* sp. nov. (*ca. mel. li'. ae* N. L. gen. n. *camelliae* of *Camellia*, fermented tea (*Camellia sinensis*) leaves, a source of the strain isolated) is proposed. The type strain is FP 15-1 ^{T} (KCTC 13133^{T}=NBRC 101868^{T} =NRIC 0105^{T} =TISTR 932^{T} =PCU 277 ^{T}).

Table 4.4. Differential characteristics of FP 15-1^{T} and related *Enterococcus* species. Species: 1, FP15-1^{T}; 2, *E. italicus*; 3, *E. saccharolyticus* DSM 20726^{T}; 4, *E. sulfureus* DSM 6905^{T}. Data for 2, 3, and 4 were obtained from Fortina *et al.* (2004). +, Positive; d, variable; –, negative; w, weak; nd, no data.

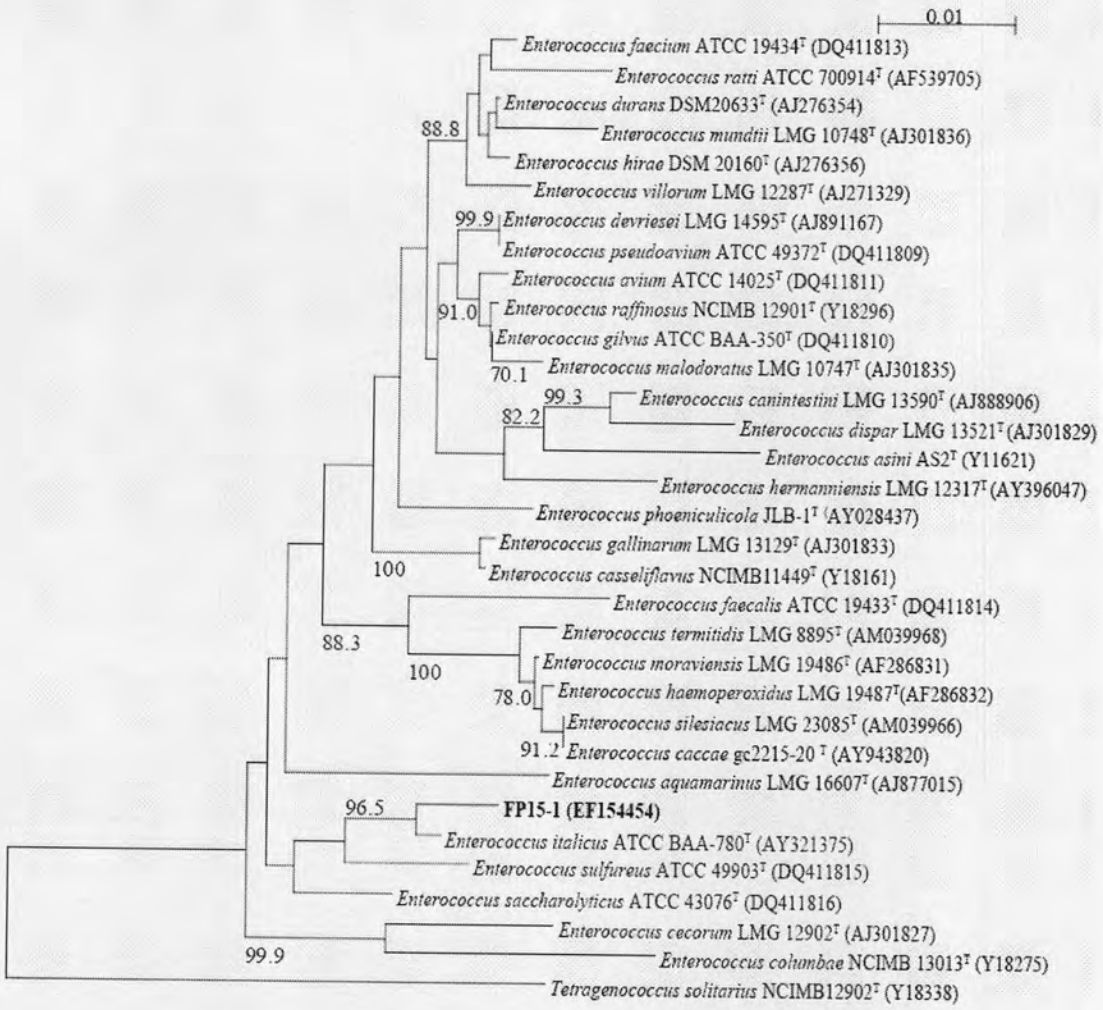

Fig. 4.6. Phylogenetic tree based on 16S rRNA gene sequences, showing the relationships between strain FP15-1^T and related bacterial species. The branching pattern was generated by the neighbor-joining method. Based on 1000 replications, bootstrap percentages less than 50 % are shown. Bar, 1 substitutions per 100 nucleotide positions.

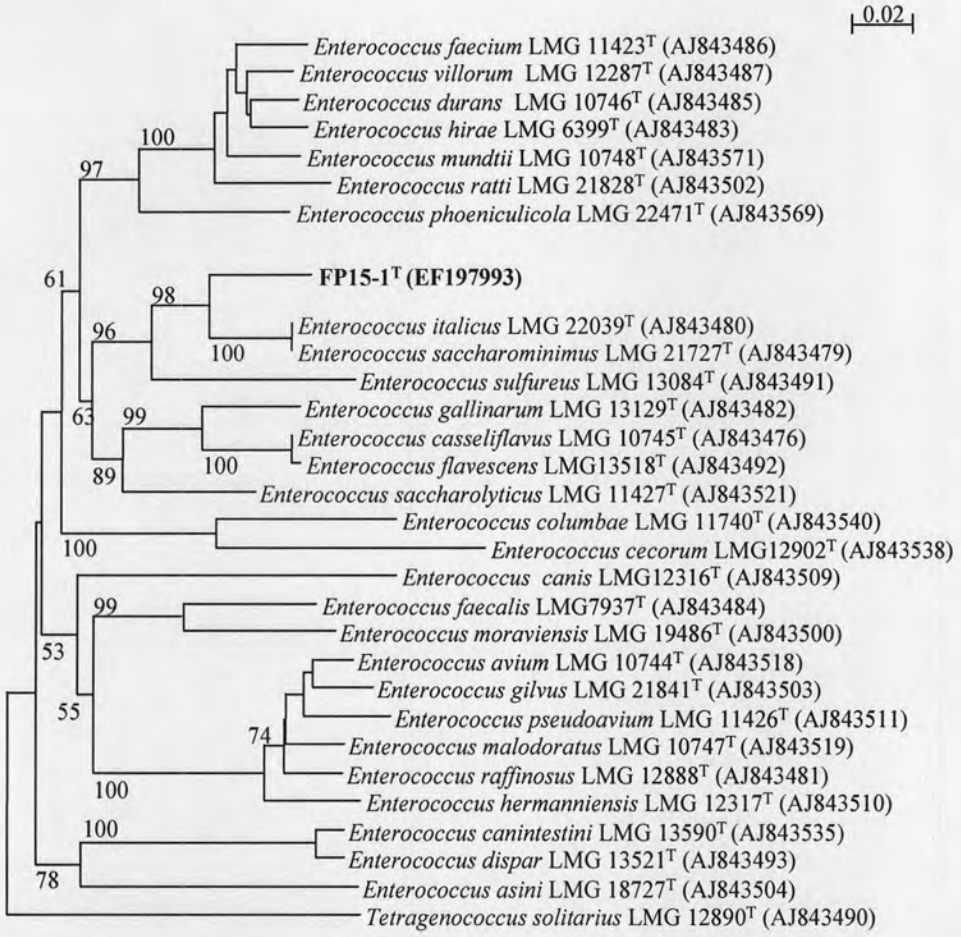

Fig. 4.7. Phylogenetic tree based on *rpoA* gene sequences, showing the relationships between strain FP15-1^T and related bacterial species. The branching pattern was generated by the neighbor-joining method. Based on 1000 replications, bootstrap percentages less than 50 % are shown. Bar, 2 substitutions per 100 nucleotide positions.

4.2.2.1 Amylase producing isolates

The selected starch hydrolyzing strains were the rods, SB2-3 and U3-1 and the coccal, N12-9 and N2-1A. The isolates were characterized as previously shown in Table 4.1 and 4.2. On the basis of the phenotypic characteristics and DNA-DNA similarity studied, the strains SB3-2 and U3-1 belonged to genus *Lactobacillus,* and the strains N12-9 and N2-1A were included in genus *Enterococcus*. Strains SB2-3 and U3-1 were identified as *Lactobacillus plantarum.* The 16S rDNA sequencing and phylogenetic analysis studied revealed that the strain N12-9 was *E. gallinarum* and N2-1A was *Enterococcus* sp. nov. On the acid production, SB2-3 and U3-1 produced high amount of acid in medium containing 5-7% starch while N2-1A did in the 2-7% starch after 5 days incubation. SB2-3 produced high acid at pH 5 after incubated for 3-5 days while U3-1 did after incubated for 3-4 days and N2-1A did at pH 6.8 for 5 days. In addition, 1% yeast extract was suitable for SB2-3 and U3-1 and N2-1A while 0.5% peptone was for SB2-3 and 1% peptone for U3-1 and N2-1A, in their acid production. DNA-DNA hybridization results of the isolates with the closely related type strains were shown in Table 4.5. 16S rRNA genes of N2-1A and N12-9 were amplified and analyzed as showed in Fig. 4.8.

4.2.3 Proteinase producing strains

The selected proteinase producing isolates were selected by ability of hydrolyzing of skim milk on agar plate. The isolates of SCR 1P and SMC 1 were rod and cocci respectively. Characteristics are previously shown in Table 4.1 and 4.2. 16S rRNA genes of the isolates were amplified and analyzed as shown in Fig. 4.9. The position of the strain SCR 1P was closely related to *Lactobacillus sakei* and the strain SMC 1 was closely related to *Enterococcus faecalis*

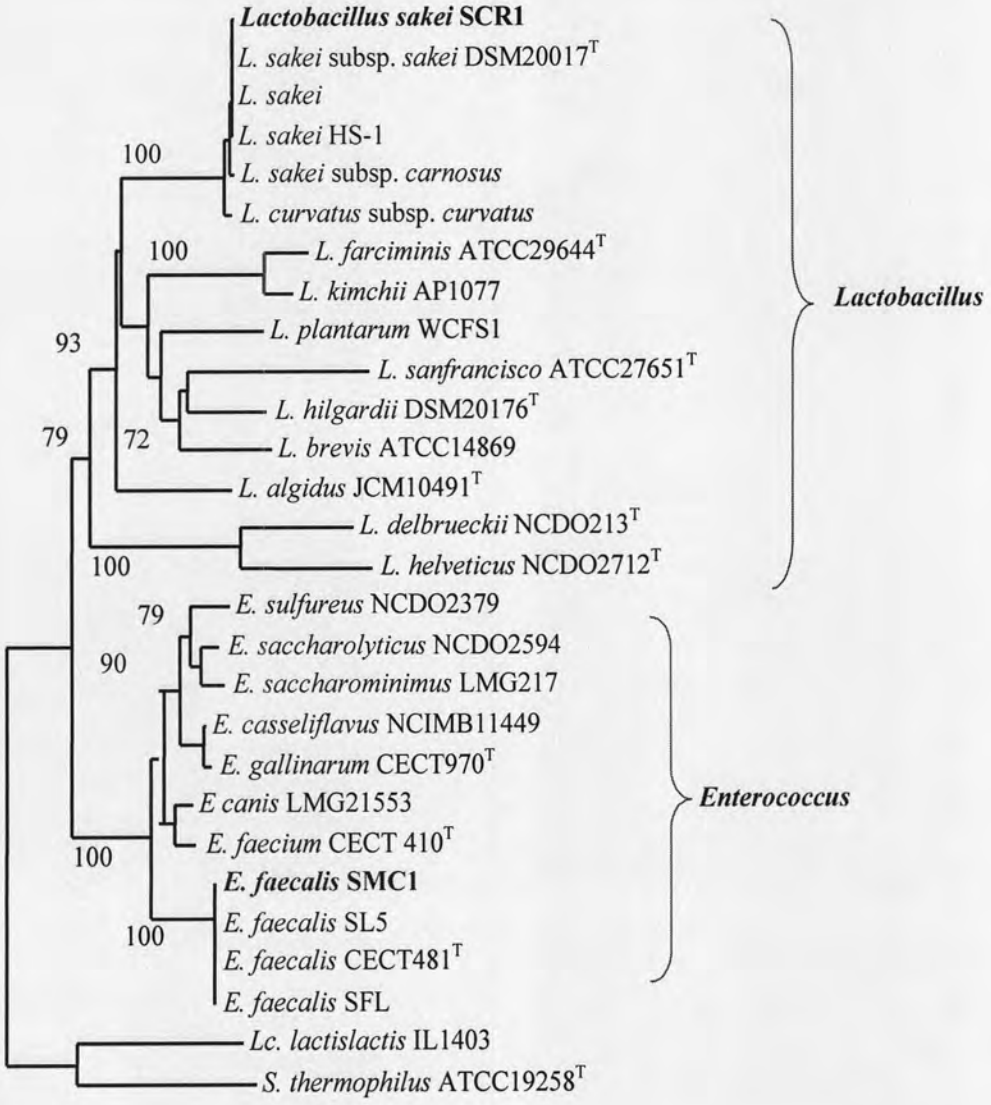

Fig. 4.9. Phylogenetic tree derived from 16S rRNA gene sequence analysis showing the position of selected amylase producing isolates SCR 1P and SMC 1 among selected lactobacilli and enterococci. The tree was generated by the neighbor-joining method. Bootstrap values based on 1000 replications are given at nodes.

4.3. Identification of Glutamate decarboxylase gene (*gadB*)

GABA-producing lactic acid bacteria isolates were examined for a glutamate decarboxylase encoding gene (*gad B*) using rapid PCR-based method. Based on search DNA data bank, five *gad B* genes of lactic acid bacteria were obtained. The PCR primers were designed from highly conserved regions of multiple alignments of the *gad B* nucleotide sequences (Fig. 4.29, including isolated genes) and presumed *gad B* encoding gene of *Lactobacillus plantarum* WCFS1 complete genome sequence. The annealing poison of *gadB* primers on L. plantarum *gadB* was shown on Fig. 4.10. Four representative strains of *L. brevis* LSF8-13 (isolated from fish fermented food, Pla-som), *L. farciminis* FS 73-1 (isolated from fish fermented food, Pla-ra), *L. plantarum* SCR 11-2 and SEA62-2 (isolated from soy sauce and pine apple, respectively) were found to have the expected 1.4 kb *gad B* gene (Fig.4.11) by using Fw &Rv GADP primers (Table 3.4). The amplified fragments were confirmed as *gad B* gene by nested PCR using inner primers of conserved regions (Fig. 4.12).

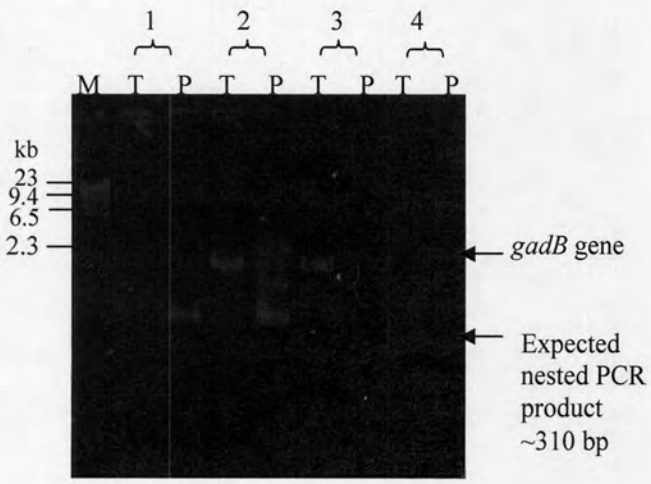

FIG. 4.12 . Confirmation of the full length amplified *gadB* of the representative strains by Nested PCR amplification using inner primers GAD2-3. Lanes: 1, LSF8-13; 2, FS73-1; 3, SEA62-2; 4, SR11-2; M, lamda DNA/*Hin*dIII marker; T, Full length amplified fragments used as template; and P, PCR product.

Interestingly, the high GABA producing strain *Lactobacillus sp.* L13 newly isolated from Japanese pickle was investigated and found to contain the different amplified PCR products pattern of *gadB* gene compared with the other isolates (Fig. 4.13). All of four representative GABA producing lactobacilli LSF8-13, FS7311, SEA62-2 and SR11-2 were found to have *gadB* gene (approximately 1.4 kb amplified fragment) proven by highly conserved regions within the gene (Fig. 4.12). In case of the high GABA producing strain LSF8-13 which was identified as *L. brevis* showed more than 4 amplified fragments using full length primers (Fig. 4.11, C, lane 1) even increasing annealing temperature. It may cause by repeat gene in genome. The expected band (~1.4 kb) were purified and confirmed as *gadB* encoding genes by nested PCR using the inner primes of conserved region.

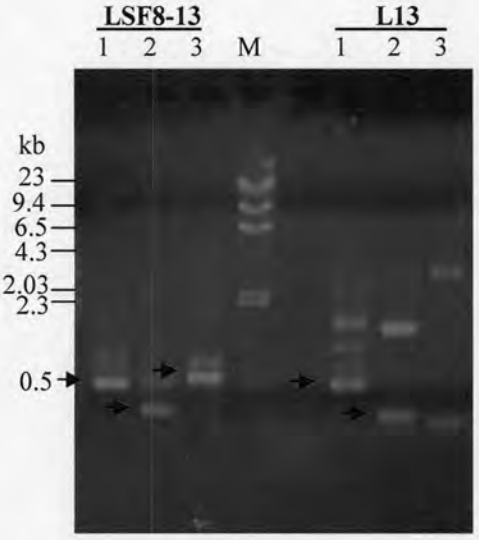

FIG. 4.13. PCR products of LSF8-13 and L13 genomic DNA amplified by inner primers of conserved regions; 1. GAD1-3; 2. GAD2-3; and 3. GAD1- 4. M: lamda DNA/*Hin*dIII marker. The expected PCR amplification products by GAD1-3, GAD2-3 and GAD1- 4 are approximate 615, 310 and 700 bp respectively. Arrowed bands are expected products.

Expected PCR product size using different inner primer sets Forward GAD1-Reverse GAD4 (GAD1-4), Forward GAD2-Reverse GAD4 (GAD2-4), Forward GAD1-Reverse GAD3 (GAD1-3) and Forward GAD2-Reverse GAD3 (GAD2-3) are 1010, 700, 620 and 310 bp, respectively. The 1.4 kb amplified product containing expected conserved region was cloned and sequenced. The nucleotide sequence

analysis of the full length amplified *Lactobacillus brevis* LSF8-13 *gadB* consisted of an open reading frame (ORF) of 1410 bases and the deduced amino acid of 469 residues showed 99 % identities to *L. plantarum* WCFS1 GAD and 49% to that of *L. brevis* IFO 12005 GAD and *L. brevis* ATCC367 GAD. The nucleotide and deduced amino acid sequences of the full length *Lactobacillus brevis* LSF8-13 *gadB* were shown in Fig. 4.14. PCR amplification of the high GABA producing *Lactobacillus* sp. L13 newly isolated form Japanese pickle using full length GAD *plantarum* primers and/or GAD *brevis* primers revealed non specific PCR products (data not shown). Using inner primers of conserved regions (GAD1-3 and GAD2- 3) showed expected bands while unexpected band was found by GAD1- 4 primers (Fig. 4.13).

The sequence analysis of the purified products of the 310 bp and 620 bp obtained from the GAD2-3 and GAD1-3 show conserved nucleotide sequence of *gadB* in *Lactobacillus* sp. L13. Phylogenetic analysis of the sequence of *gadB* genes (~620 bp) of representative isolates comparing with known *gadB* was shown in Fig. 4.14. The full length GAD *plantarum* CDS and *bre* GAD primers were used in combination of the different species: *bre* GAD forward – Rev GAD *plantarum* CDS and Forward GAD *plantarum* CDS – *bre* GAD Reverse were used to amplification of the full length *gadB* of *Lactobacillus* sp. L13. No amplification products were gain.

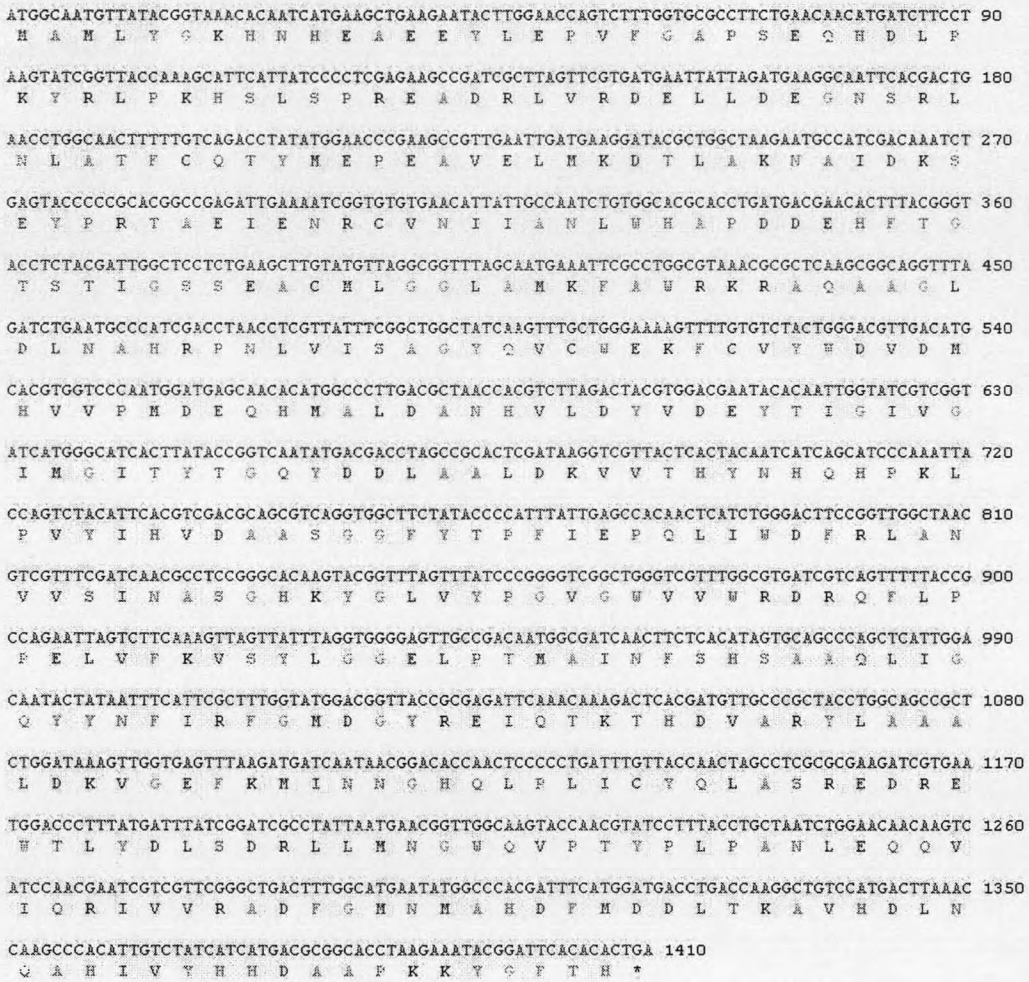

Fig. 4.14. The nucleotide and deduced amino acid sequences of the full length *gadB* of *Lactobacillus brevis* LSF8-13

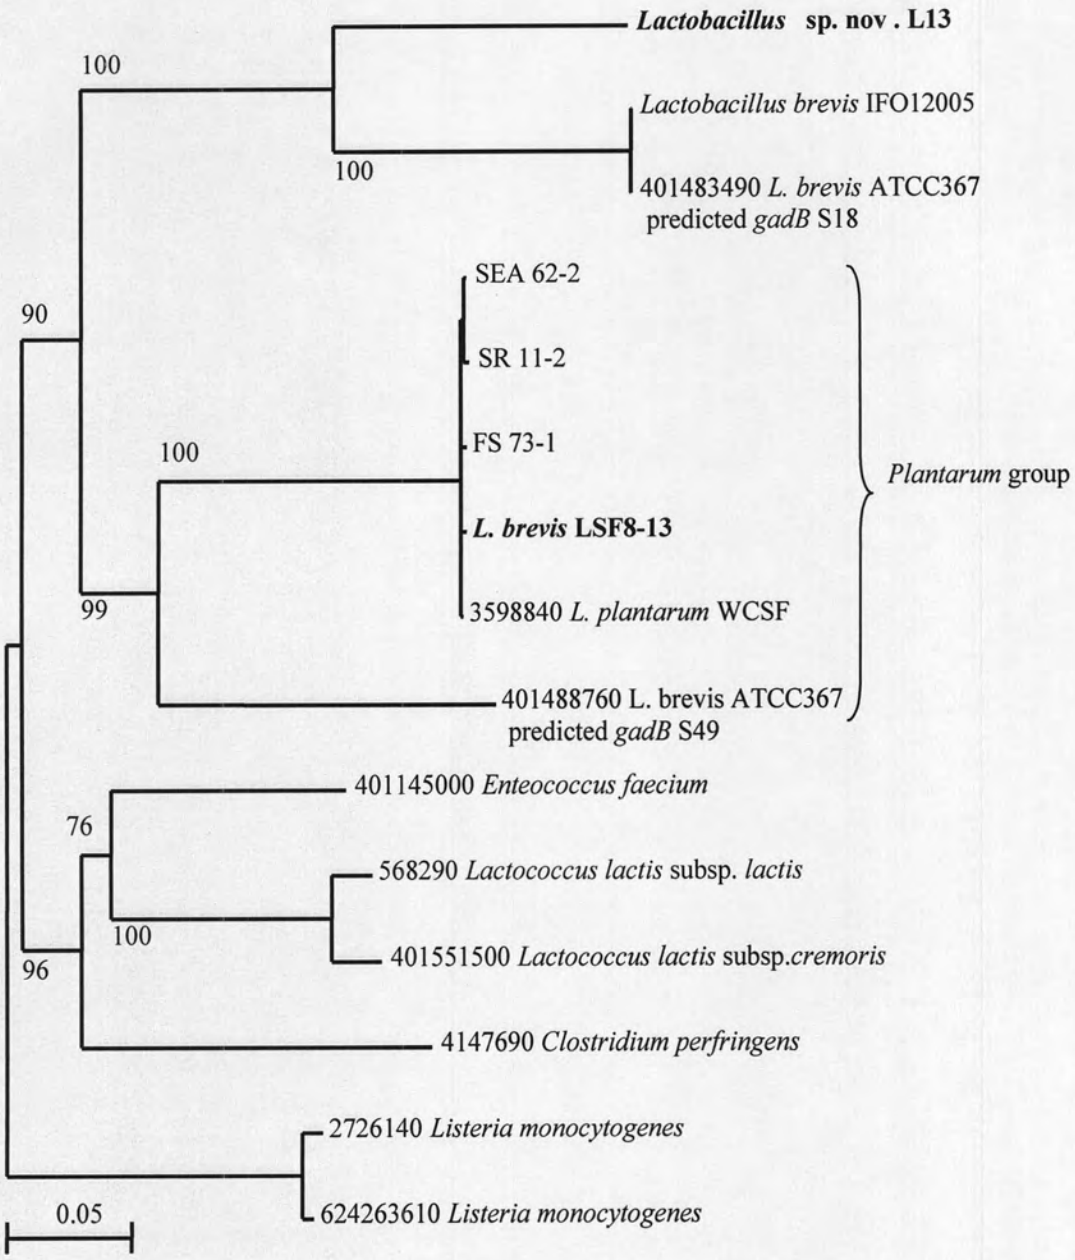

Fig. 4.15. Phylogenetic analysis of the conserved regions (~615 bp) of glutamate decarboxy lase genes (*gadB*) of representative isolates comparing with known *gad*B.

4.3.1 TAIL-PCR for identification of the novel glutamate decarboxylase gene from the novel isolate of *Lactobacillus* sp. L13

The inner primers of conserved regions in combination with the full length GAD *plantarum* CDS, *bre* GAD primers and inner primers of conserved regions (Table X) were investigated. Approximately 810 bp and 1,800 bp PCR product was obtained from *bre* GAD Fw and Reverse GAD3 (Fig. 4.16). The bands were purified, cloned into pGEM-T easy and sequenced. The sequence analysis of the ~810 bp band showed conserved among *gadB* .

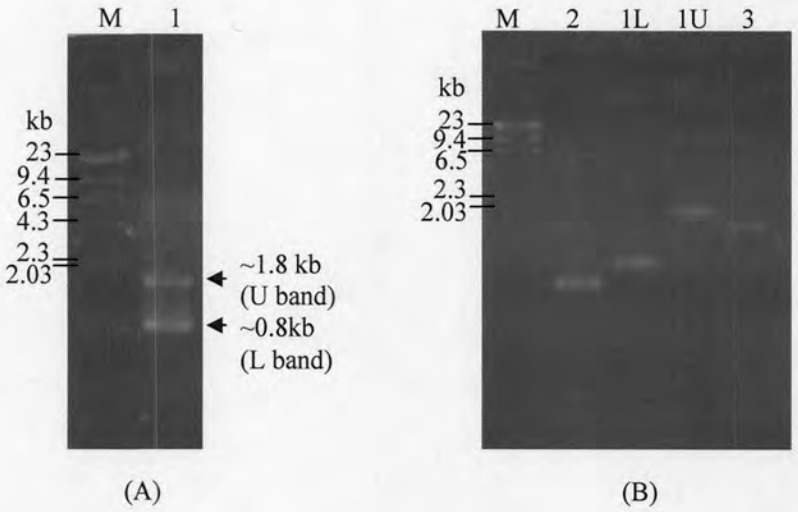

Fig. 4.16. Amplification products of *Lactobacillus* sp.nov.L13 using species combination primers of *bre* GAD Fw and Reverse GAD3 (lane 1A). M: lamda DNA/*Hin*dIII marker. The arrowed bands were purified as showed in (B) lane 1L (~0.8 kb) and 1U (~1.8 kb). Lane 2: purified band of L13 GAD1-3 which will be DIG-labeled and used as probe for hybridization, Lane 3: purified band of full length *gadB* of LSF8-13.

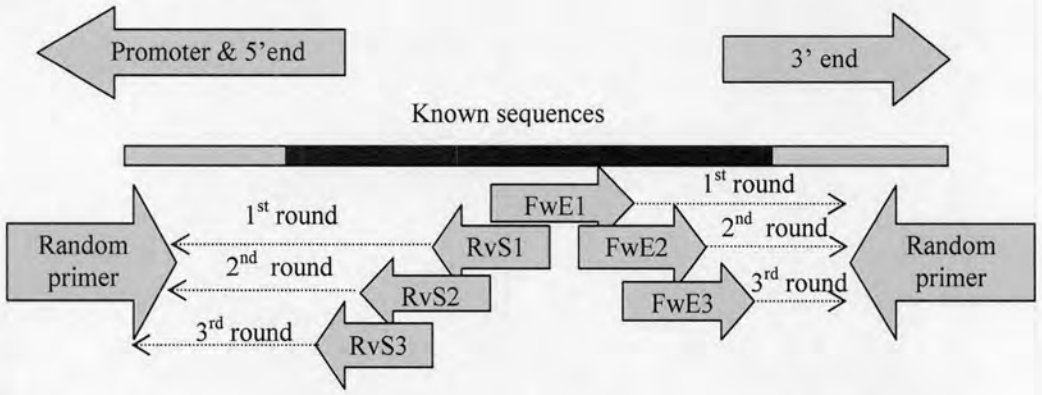
The specific PCR primers for TAIL-PCR were designed from the 810 bp known sequence to get the 3'end and 5' end including the promoter and ribosome binding site. TAIL-PCR were performed using different random primers in combination with specific primers. The strategy to get the whole gene by using TAIL-PCR method was shown in Scheme. 4.1. PCR primers used for TAIL-PCR methods were showed in Table. 3.6. Purified band of L13 GAD1-3 (Fig. 4.16.(B) land 2) was labeled and used as probe for detection of TAIL-PCR products and copy number of *gadB* gene in L13 genome.



Scheme 4.1. The schematic outline to obtain the whole *gadB* from *Lactobacillus* sp. L13 by using TAIL-PCR method

The 3' end region was successfully amplified by the random primer AD3 and Nini256 in combination with specific forward primers (FwE1, FwE2, FwE2N, FwE3, and FwE3N) subsequently. The expected amplified products decreased in size gradually. The amplified bands were detected by hybridization with the 610 bp probe of L13 GAD1-3 then the detected bands (Fig. 22) were cloned, sequenced and searched for overlapping region with the known sequences. L13_917 and L13_1151 primers (Table. 3.6) were designed from the revealed sequence and used as sequencing and specific primers in combination with the random primers walking at 3' end to obtain and confirm stop codon of the *gadB* gene of *Lactobacillus* sp. L13

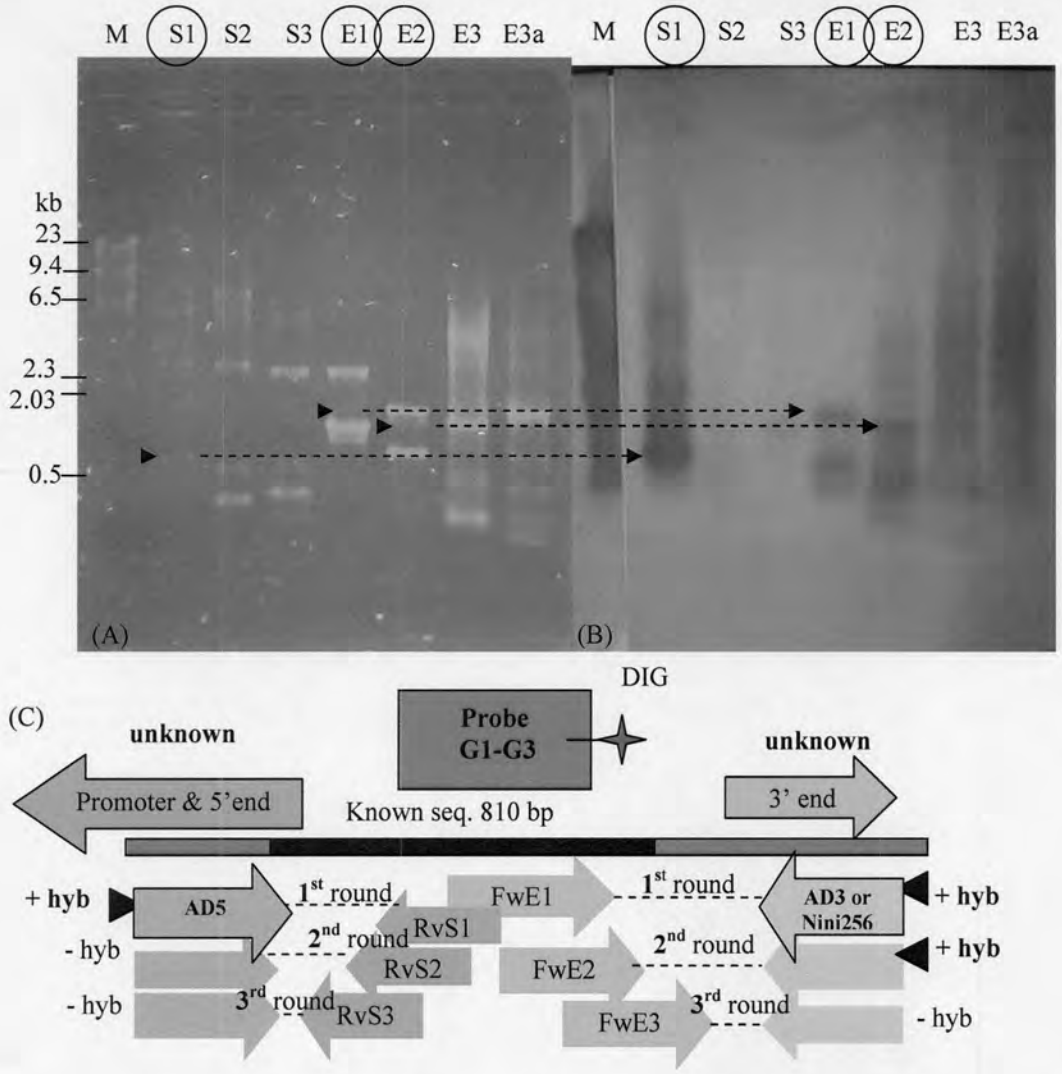


Fig. 4.17. TAIL-PCR amplification products (A) and results of hybridization (B) the arrowed bands showed positives signal of the hybridized bands of TAIL-PCR products of RvS1, E1 and E2. The scheme (C) shows strategy of the detection method. The RvS2, RvE3 and FwE3N products are out of regions to be hybridized by the probe G1-G3.

PCR amplification of full length gadB gene from *Lactobacillus* sp. nov L13 were investigated by reverse primers of L13_Rv1413 (Table 3.6) which was designed from 3' end revealed result of TAIL-PCR in combination with *bre* GAD Fw primer (Table 3.4). The PCR products was a single band with expected size of approximately 1.4 kb (Fig. 4.18) confirmed specificity of the primer used then the band were purified, cloned and sequenced to confirm the 3' end region of the *gadB*. However, the amplified gene may contains mismatch bases at the start codon caused by the different species of *bre* GAD Fw primer. The 5' end of the gene should be identified and confirmed.

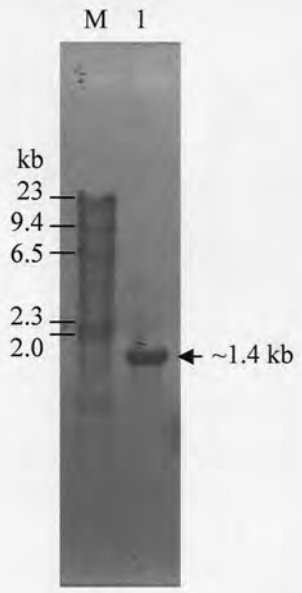

Fig. 4.18. Specific amplified PCR product of *Lactobacillus* sp. nov L13 *gadB* using *bre* GAD Fw and L13_Rv1413 primers

The 5' end region was obtained by the random primer AD5 in combination with specific forward primers (RvS1, RvS2 and RvS3 respectively). The RvL13_155 primer (Table 3.6) was designed from the revealed sequence and used as sequencing and a specific primer in combination with the random primer AD5 walking at 5' end to obtain and confirm start codon and promoter regions of the *gadB* gene of *Lactobacillus* sp. L13. The amplified bands were hybridized with 230 bp DIG-label probe of *bre* GAD Fw- RvS2, cloned, sequenced and searched for overlapping region with the known sequences.

The start codon was found to be ATG. The predicted promoter and ribosome binding site were found by promoter prediction programs, PPP (Prokaryote Promoter Prediction, http://bioinformatics.biol.rug.nl/websoftware/ppp/)and BPROM (Bacterial sigma70 promoter recognition program http://www.softberry.com). Sequences data were aligned. The full length *Lactobacillus* sp. L13 *gadB* consisted of an open reading frame (ORF) of 1437 bases and encoded a protein of 478 amino acid residues.

The deduced amino acid sequenced was searched for the conserved domain compared with others GAD in the conserved domain database. The deduced amino acid sequence shown conserved domain of pyridoxal-5'- phosphate decarboxylase and glutamate decarboxylase at the middle of the gene (Fig. 4.19). The nucleotide and

deduced amino acid sequences of the full length *Lactobacillus* sp. L13 *gadB* including predicted promoter regions were shown in Fig. 4.20.

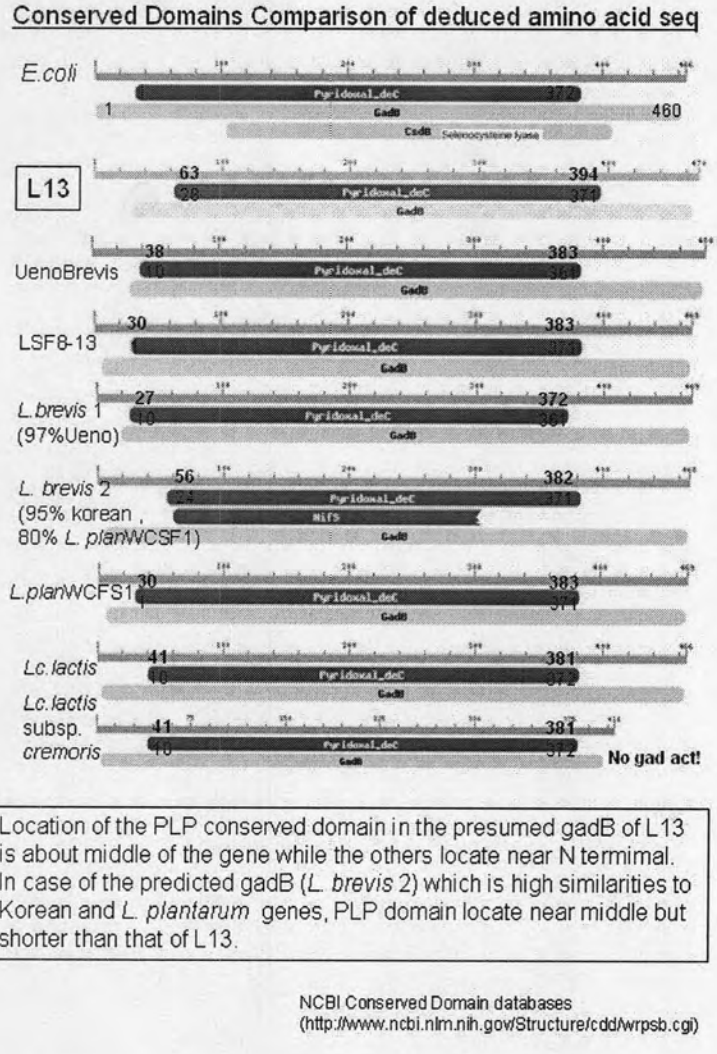

Fig. 4.19. Comparison of conserved domain comparison among glutamate decarboxylases from different species.

Fig. 4.20. The nucleotide and deduced amino acid sequences of the full length *Lactobacillus* sp. L13

The 1437 bp full length amplified fragment of *Lactobacillus* sp. L13 *gadB* was DIG-labeled and used as a hybridization probe for detection of *gadB* on the genome. *Lactobacillus* sp. L13. Genomic DNA was digested with restriction enzymes and subjected to Southern blotting (Fig. 4.21). A single band was detected with *Bam* HI, *Eco*R I, *Hind* III, and *Pst* I digested. Suggested, there is only one glutamate decarboxylase gene in the genome of *Lactobacillus* sp. L13.

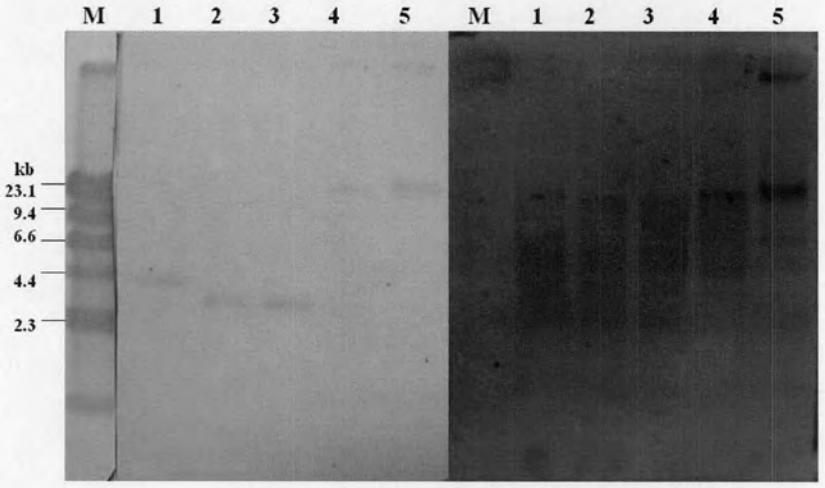

Fig. 4.21. Southern blot analysis of *Lactobacillus* sp. L13. The DNA was digested with *Bam* HI (lane 1), *Eco*R I (lane 2), *Hind*III (lane 3), *Pst* I (lane 4) and Uncut DNA (lane 5). The blot was probed a digoxigenin-labeled 1.4 kb *Lactobacillus* sp. L13 *gadB* amplified fragment.

4.3.2 Restriction analysis of the identified *gadB* of *Lactobacillus* sp. nov. L13 and *L. brevis* LSF 8-13

The revealed sequences of the *gadB* were restriction analysis using Bioedit program version 1.83. The restriction analysis of gadB from *Lactobacillus* sp. nov. L13 and *L. brevis* LSF 8-3 by 6 bases-cutter enzymes were list in Table 4.6. and 4.7, respectively. Enzymes that do not cut the genes will be selected for further experiments of subcloning and construction of expression clone. Enzymes that cut the gene will be used for restriction analysis of the recombinant clones.

Bgl II cannot be used for construction of expression clone of *gadB* of *L. brevis* LSF 8-13 since this enzyme cut the gene so *Sph* I and *Bam* HI were selected to be used as adapter restriction size for subcloning.

4.4. Construction of vector for expression of *gadB* from *Lactobacillus* sp. nov. L13 and *Lactobacillus brevis* LSF8-13

The *L. brevis* LSF8-13 and *Lactobacillus* sp. nov. L13 *gadB* open reading frame was re-amplified for restriction modification of 5' and 3' end adding of *Sph* I and *Bam* HI restriction site (Table.4.8, LSF8-13Fw*Sph*I & LSE8-13Rv*Bam*HI and L13Fw*Sph*I & L13Rv*Bam*HI). The synthetic primers with restriction site were also designed to control the inserted gene to be in frame by adding nucleotides and the stop codon of the genes were omitted. The modified *gadB* fragments were cloned into pGEMT-Easy (Promega). The recombinant clone of *Lactobacillus* sp. L13 and *gadB* *L. brevis* LSF8-13 with *Sph* I and *Bam* HI were subjected for restriction cut for preparation of insert for construction of expression plasmid.

Table 4.8. PCR primers used for cloning of *gadB*

Amplification	Primer name	Sequence (5'-3')	Tm (°C)

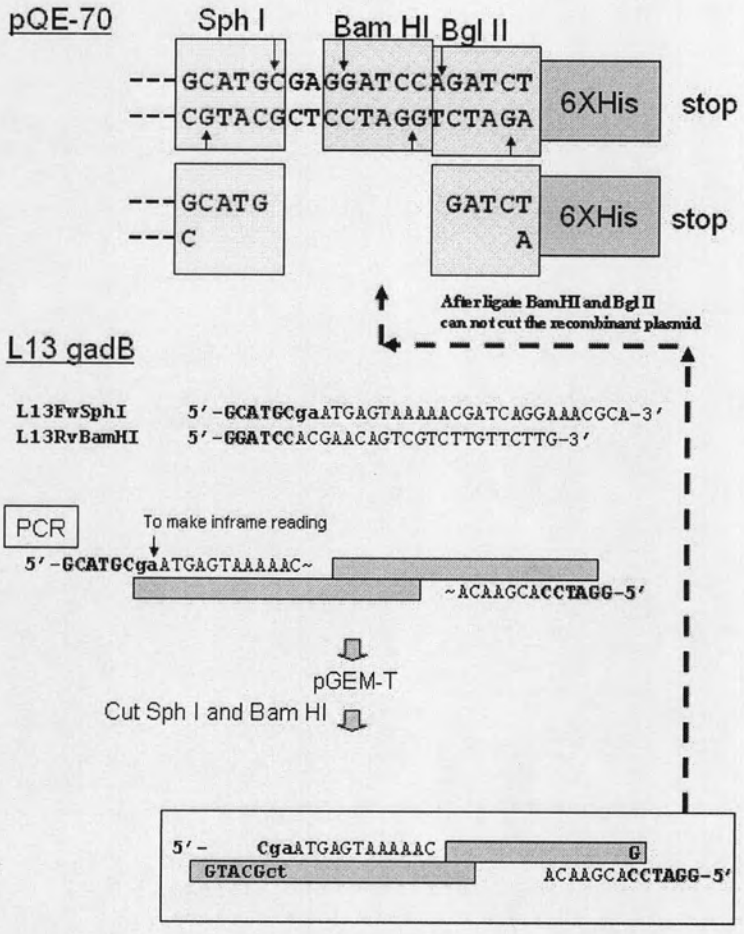
The recombinant plasmids of *Lactobacillus* sp. L13 *L. brevis* LSF8-13 *gadB* in pGEM-T easy were subjected for sequencing analysis to confirmed the inserted genes then the clones will be cut with *Sph* I and *Bam* HI and subcloned into vector pQE70 double cut with *Sph* I and *Bam*HI, for expression under the control of the *lac* promoter and for purification of 6xHis-tagged recombinant GAD. The strategy to construct the expression clone is shown in scheme 4.2. The recombinant clone was checked for the size of recombinant plasmid and by restriction analysis (Fig.4.22) The recombinant expression plasmids which contained the inserted gene of interest were sequenced to confirm the gene and its reading frame and the histidine-tagged at the end of the genes



Scheme 4.2. The strategy to construct the expression plasmid of *gadB* from *Lactobacillus* sp. L13 in pQE-70 histidine-tagged expression vector.

The recombinant clones for expression of *Lactobacillus* sp. L13 *gadB* were first cut with *EcoR*I to avoid for contamination of pGEMT-Easy vector that the plasmid will be cut twice and two bands of 3 kb and 1.4 kb will be found (Fig.4.22) Recombinant clones the strain L13 and LSF 8-13 were analyzed by cutting with restriction enzymes (Fig. 4.23 and 4.24, respectively).

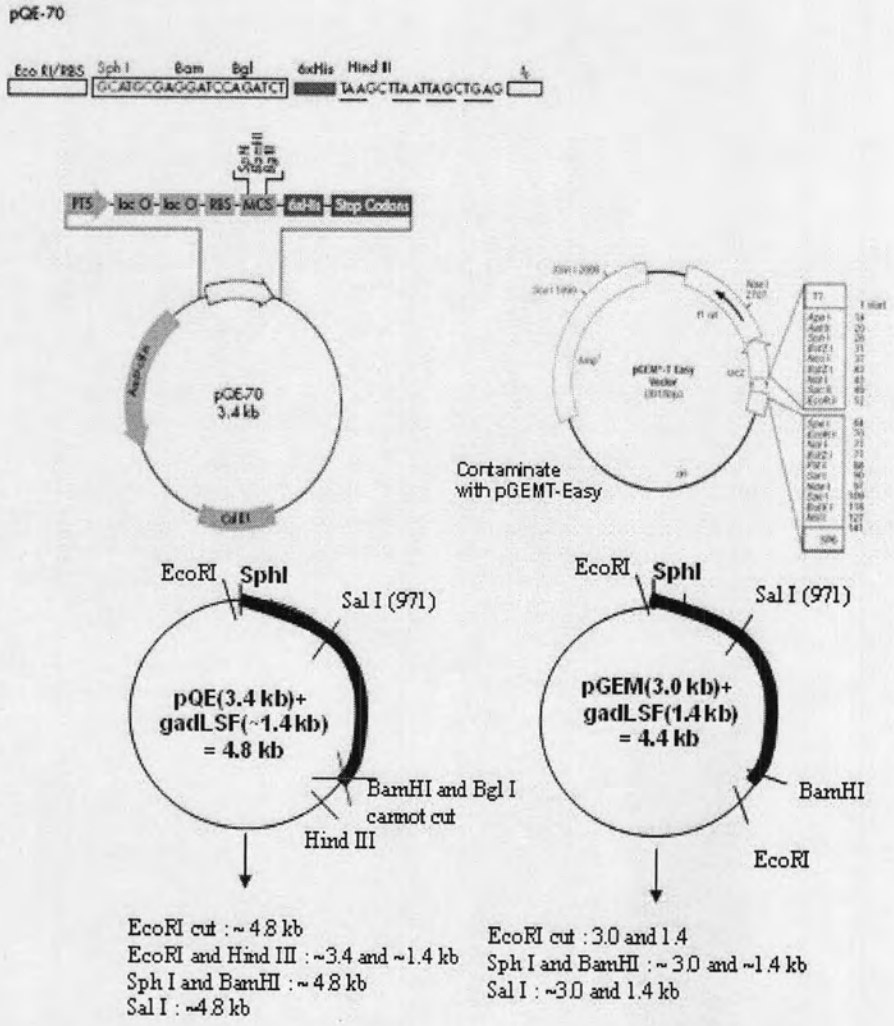


Fig. 4.22. Map of plasmid pQE-70 and pGEMT-Easy with inserted gene of L13 *gadB*.

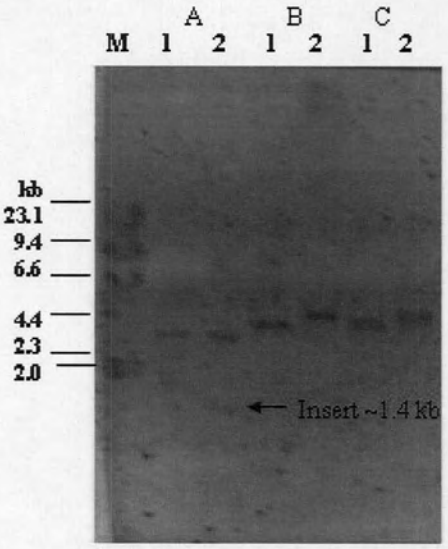

Fig. 4.23. Restriction analysis of the recombinant plasmids extracted from clone number 1 and 2. of the L13 strain. A, double cut with *EcoR* I and *Hind*III. B, double cut with *Sph* I and *Bgl* II. C, cut with *Sal* I .

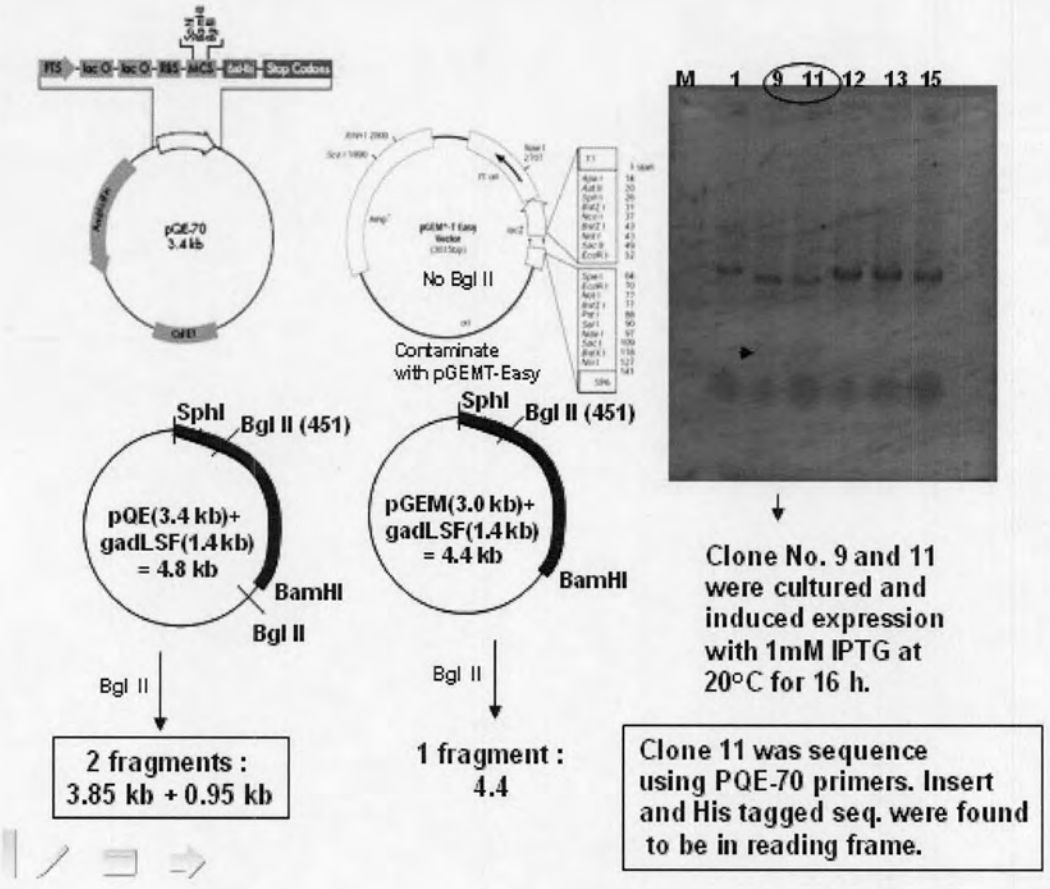

Fig. 4.24. Map of restriction analysis of the recombinant clones of the strain LSF8-13 *gadB* in pQE-70 and the result of restriction analysis of the selected clones.

Recombinant *gadB* clones of both LSF8-13 and L13 were sequenced to confirm the coding sequences and reading frame. The clone were sequenced using specific primer for the expression vector pQE70

4.5. Expression and purification of *gadB* from *Lactobacillus* sp. nov. L13 and *Lactobacillus brevis* LSF8-13

First of all, GABA producing activity of the isolated strains *Lactobacillus* sp. nov. L13 and *Lactobacillus brevis* LSF8-13 were compared by TLC (Ueno et al., 1997). The isolates were cultured in GYP medium supplemented with 1-5% glutamic acid of 5 days. The culture supernatants of each day were analyzed by TLC. The strain L13 showed high level of GABA productivity. 5% of glutamic acid in culture medium of strain L13 was completely converted to GABA within 48 h of incubation at 30°C while the strain LSF8-13 changed 1% glutamic acid to GABA by 2 days of incubation at the same condition. Next step, the two recombinant clones of LSF8-13, GABA producing activity from crude extract of clones were checked in comparison with the crude extract activity of the wild type *Lactobacillus* sp. L13, the extract of host *E.coli*, and purified fractions of the clones through HiTrap affinity column charge with Ni^{2+} ion as shown in Fig. 4.25. The Gad activity assay was performed as described previously in Chapter III. Ammonium sulfate was added to reaction mixture for testing of the effect of sulfate ion on Gad activity as the activity of *L. brevis* has been influenced by the ammonium sulfate in the reaction mixture (Ueno *et al.*, 1997). The ammonium sulfate had no significant effect on Gad activity of the crude extract of L13 (spot no. 2 & 3 in Fig 4.25). The clones of LSF8-13 had no activity of Gad comparing with the host *E. coli*.

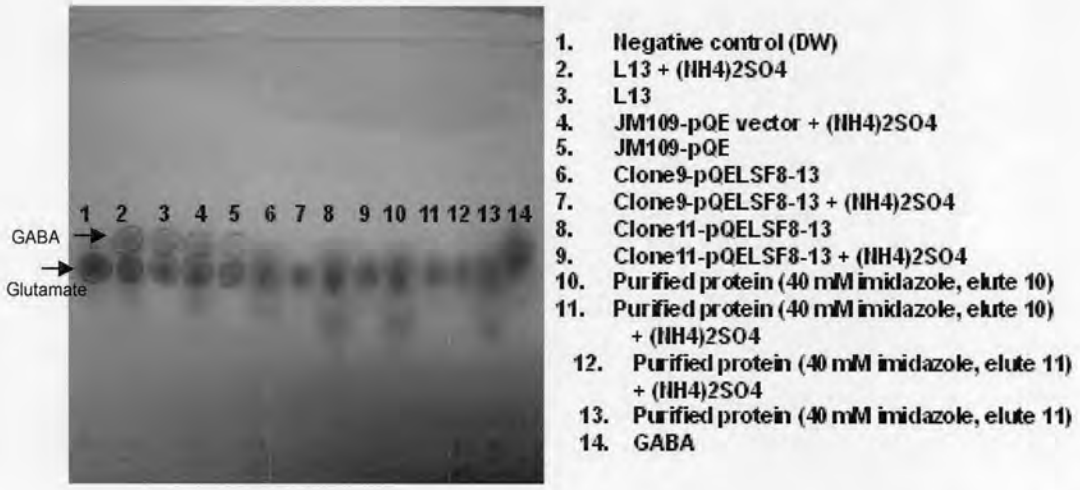

Fig. 4.25. TLC analysis for glutamate decarboxylase activity to catalyses L-glutamic acid to γ-aminobutyric acid (GABA)

After getting the expression of L13 and the complete sequence of the identified gene were confirmed, Gad activity of the recombinant clones of both L13 and LSF8-13 were again investigated of GABA productivity by modified decarboxylase test (LB agar supplemented with 0.05 % glucose, 100 μg/ml ampicillin,1% glutamic acid, 0.5% PLP and 0.001% bromothymol blue indicator). pH of medium was adjusted to 7.0 to get blue color. 0.01 M IPTG were added after sterile. After 1 day of incubation, the media turned yellow with gas production. The recombinant clone of L13 shown high activity in production of gas. The medium again turned blue (Fig. 4.26). Crude extract of the clones were checked for GABA productivity on TLC plate (Ueno *et al.*, 1997) in compared with crude extract of host *E. coli* as shown in Fig. 4.27. Requirement of PLP were investigated. The recombinant clone of L13 showed Gad acitivity depending on the present of PLP in reaction mixture clearly different from the background activity of the host *E.coli*. The Gad activity of recombinant clone of LSF8-13 was not detected.

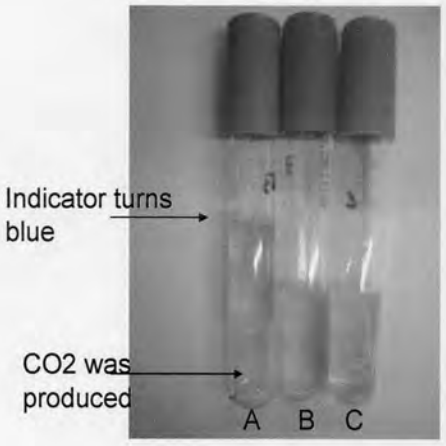

Fig. 4.26. Gad activity detection of the recombinant clones in modified decarboxylase medium containing 1% glutamic acid. A. clone L13, B. clone LSF 8-13, and C. host *E. coli* harboring pQE70 without inserted gene. The recombinant clone L13 *gadB* shown high activity in producing of CO_2 gas and the indicator turned back to blue color.

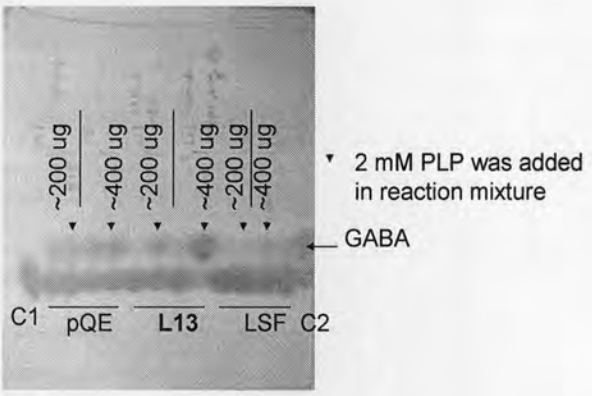

Fig. 4.27. The TLC plate analysis of GABA production by activities of the recombinant clones L13 and LSF 8-13 *gadB* comparing with the host E. coli containing pQE70 vector without inserted gene. C1 and C2 are glutamic acid and mixed glutamic acid-GABA used as standard control. The crude extract of the clones were mixed with the reaction with/without PLP. The crude protein concentrations were 200 and 400 μg, respectively. The clone L13 shown high GAD activity with PLP in reaction mixture clearly discriminated from the background of the host *E.coli.*

The clones were then induced with 0.01 mM IPTG at 25 ^{o}C for overnight (18 h). Cell pellet were collected by centrifugation and lysed by Multi-Beads shocker. The supernatant and cell debris were separated by centrifugation. The crude extract of induced, non-induced clones and host JM109 with an empty plasmid pQE70 were preliminary checked and compared the crude protein patterns on SDS-PAGE. Crude extract of the induced clone were found to contain an expressed protein band compared with that of the host cell (data not shown) then 6xHis-tagged recombinant *gadB* in the crude supernatant was loaded through HiTrap affinity column charge with Ni^{2+} ion. The eluted protein were collected and loaded onto SDS-PAGE. The SDS-PAGE analysis of the recombinant clone of strain L13 (pQE70-L13 *gadB*-histagged) in *E.coli* JM 109 (Fig. 4.28) showed the expressed protein in crude extract (lane C) and a single band of purified protein (lane E1 & E2) of approximately 59 kDa. Protein concentration of crude protein, flow through, wash, and elute fractions were quantified by Bradford method (Bradford, 1976). The Gad activity of the purified

enzyme (E1&E2) can be detected on TLC plate. The recombinant clone of strain LSF 8-13 was induced expression, purified and analyzed. The purified LSF 8-13 recombinant protein was also approximately ~56 kDa with no activity was detected (data not shown).

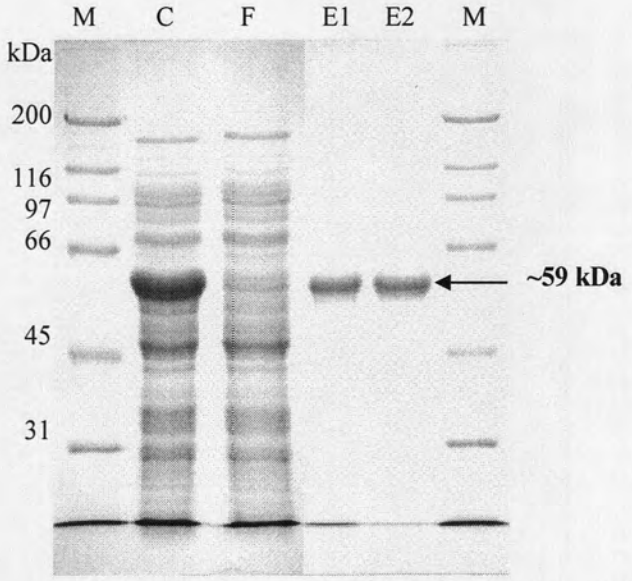

Fig. 4.28. SDS-PAGE analysis (12 % w/v gel) of the purified GAD of *Lactobacillus* sp. nov. L13 induced expression in E.coli JM109. Lane M. broad range SDS-PAGE standards (Biorad) with their size listed in kilodalton (kDa), C. crude extract of JM109 harboring plasmid pQE-70-L13 *gadB* , F. HiTrap-Ni column flow through of , E. purified protein GAD eluted by 100 mM imidazole. The calibration curve of protein standards was in appendix III.

4.6. Comparative analysis of the isolated *gadB*

Identity and similarity (%) of DNA sequence (1326 bp) and amino acid sequence (449 residues) of L13 with others are shown in Table 4.9. The multiple alignment of *gadB* available in database including our data were performed both gene and deduced amino acid. Alignments of nucleotide sequence and deduced amino acid sequence of L13 with others are shown in Fig. 4.29 and 4.30, respectively.

Table 4.9. Percent identity and similarity of DNA sequence and amino acid sequence of L13 with others related genes.

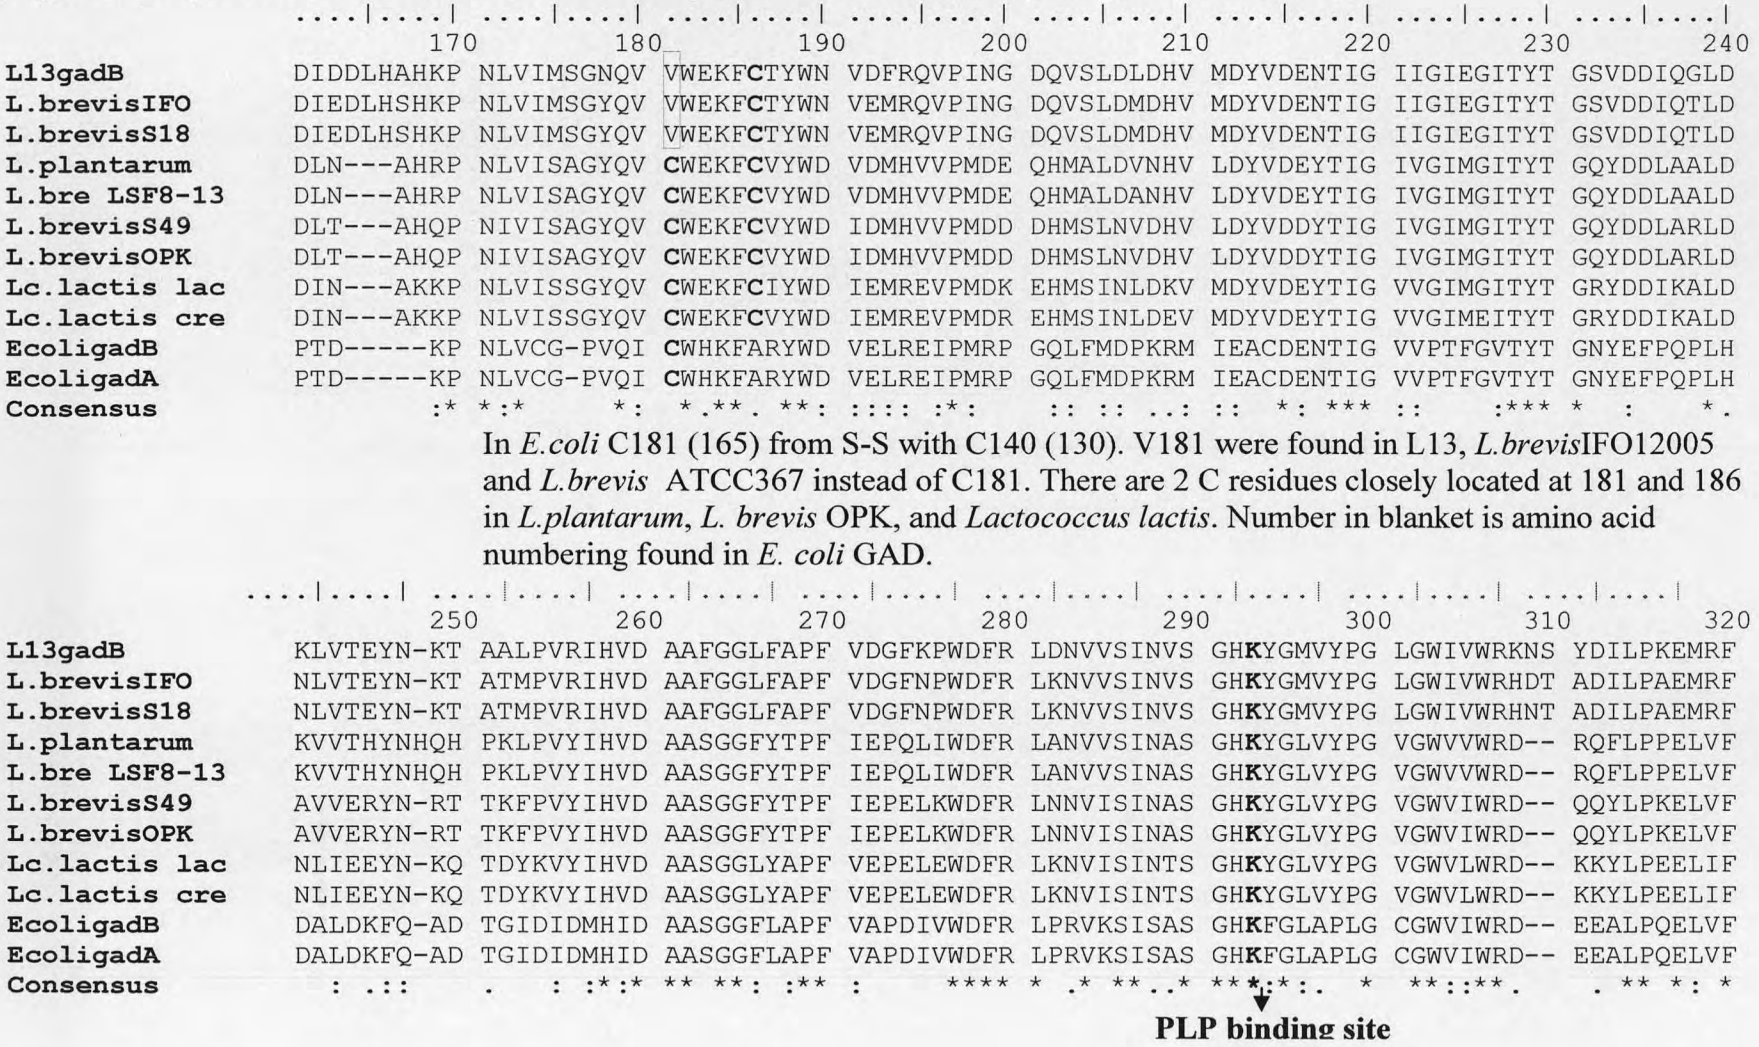
D94 is the important residue for substrate binding and loop taking up while C140 (130) from S-S with C181(165) in *E.coli* GAD. Number in blanket is amino acid numbering found in *E.coli* GAD.

Fig. 4.30. Alignment of deduced amino acid from glutamate decarboxylase gene (*gadB*) (continued)



In *E.coli* C181 (165) from S-S with C140 (130). V181 were found in L13, *L.brevis*IFO12005 and *L.brevis* ATCC367 instead of C181. There are 2 C residues closely located at 181 and 186 in *L.plantarum*, *L. brevis* OPK, and *Lactococcus lactis*. Number in blanket is amino acid numbering found in *E. coli* GAD.

4.7 3D structure analysis

The deduced amino acid sequence of isolated *gadB* from *Lactobacillus* sp. L13 and *L. brevis* LSF8-13 and that of *Lactobacillus brevis* IFO12005 (Ueno *et al.* unpublished data) were submitted to 3D –JIGSAW server program (Bates *et al.* 2001) at http://www.bmm.icnet.uk/servers/3djigsaw/. The submitted amino acid were analyzed and changed to protein data bank (pdb) format. The pdb file were view by RasWin 2.7.3.1 molecular graphics visualization tool (http://www.rasmol.org). The 3D structures were compared and shown in fig 4.31.

Fig.4.31 3D structure of GAD proteins from the strain IFO12005, L13, and LSF8-13. The number of predicted H-bonds, helices, strands, and turn of each protein were shown under their structure.

The structures were rotated, compared, and marked for PLP-binding domains, predicted active sites and/or different residues. Variation sites were found at the N-terminal loop. PLP-binding lysine (K) residues were located at 288 and 289 in the strain L13 and IFO12005 respectively (Fig. 4.32). Deletion residues at 121 and 122 were deleted in the unexpressed GAD of the strain L13. Difference were found at these residues in the strain L13 and LSF8-13. Glycine (G) 121 was found in L13 while tyrosine (Y) 122 was found in IFO12005. Difference loops and residues were marked and shown in Fig 4.32 and 4.33.

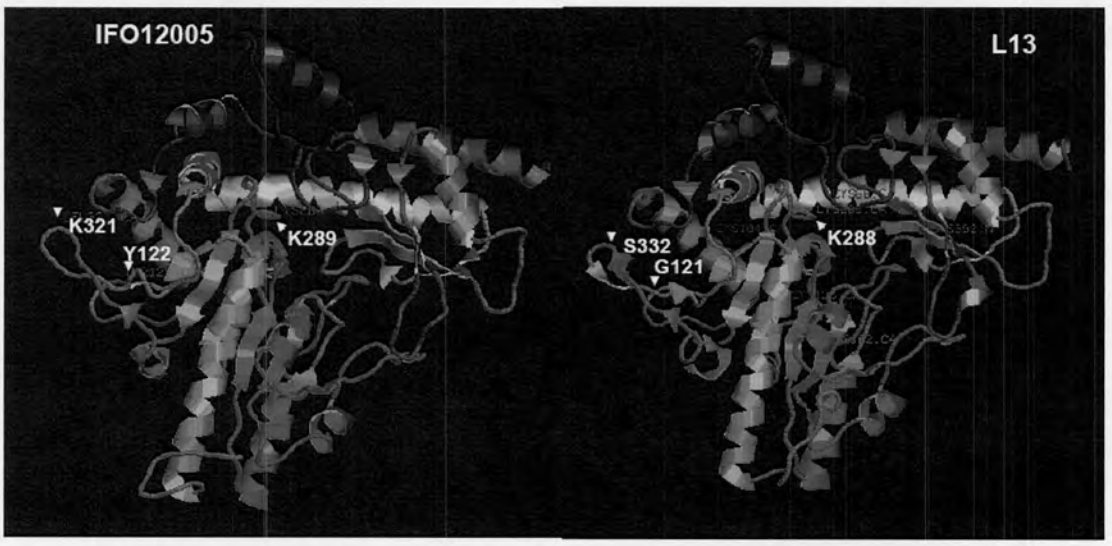

Fig 4.32 PLP-binding lysine (K) residues and different residues on loop structure of the strain L13 and IFO12005 which were deleted in unexpressed GAD of strain LSF8-13

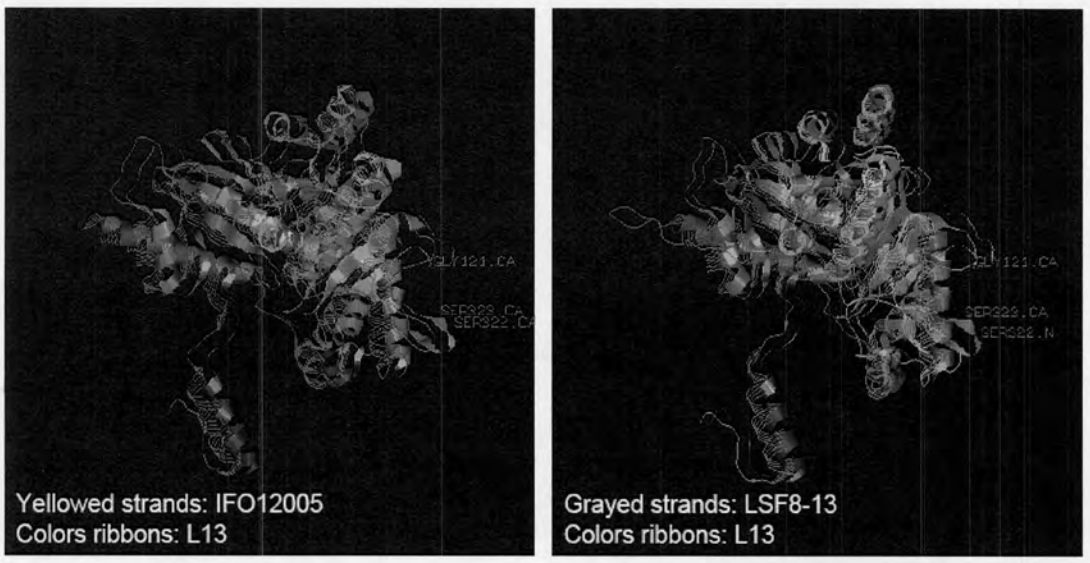

Fig 4.33 Superimposed structure of L13 compared with that of IFO12005 and LSF8-13 shown difference residues at the right side loops structure.

By comparison of the 3D models and alignment of deduced amino acids, the residues phenylalanine (F) 120 and glycine (G) 121 in the strain L13 seem to be important residues since this position was different in the lower GABA producing strain of IFO12005. Isoleucine (I)121 and tyrosine (Y) 122 were found in IFO12005. Interestingly, deletions of these residues were found in that of the unexpressed LSF8-13 GAD. These residues were predicted to from loop structure and found to locate near another loop which consisted of variable residues among compared GADs. Two serine (S) 322 and 323 were found in L13 while lysine (K) 321 and threonine (T) 322 were found in IFO12005, these residues were found to from loop closed to the previously mentioned loop. The residues were labeled as shown in Fig 4.32 and 4.33. These residues should be further studies by mutation to confirm their important properties in catalyze of glutamate to GABA.
