6171003063 : MAJOR PETROCHEMICAL TECHNOLOGY

KEYWOR Palm fatty acid distillate (PFAD)/ Bio-jet fuel/ Deoxygenation/

D: Cobalt/ Palladium/ HZSM-12 zeolite/

Jarujit Chaowichitra : Production of Bio-jet Fuel from Palm Fatty Acid Distillate over Bi-functional CoPd/HZSM-12 Catalysts. Advisor: Assoc. Prof. SIRIPORN JONGPATIWUT, Ph.D.

Jet fuel is one of the major products from a petroleum refinery, its combustion emissions contribute to global warming. Therefore, bio-jet fuel is introduced to solve this problem. Palm fatty acid distillate (PFAD) is an interesting feedstock for bio-jet fuel production via three reactions including deoxygenation, hydrocracking, and isomerization. In this study, the monometallic (Co and Pd) and bimetallic (CoPd and NiPd) supported on HZSM-12 zeolite with various metal loadings and bimetallic CoPd with various zeolite supports (HZSM-12, HZSM-5, and HY) were investigated in a continuous flow trickle bed reactor. The presence of bimetallic CoPd on HZSM-12 zeolite support enhanced the deoxygenation activity and acidity for bio-jet fuel production. Moreover, 10Co1Pd/HZSM-12 exhibited high stability due to its low coke formation. 10Ni1Pd/HZSM-12 catalyst showed high deoxygenation reaction but low hydrocracking thus it produced a high amount of biodiesel. The 10Co1Pd/HZSM-5 catalyst had high acidity which excessively cracked, resulting in a low quantity of bio-jet fuel, while the 10Co1Pd/HY catalyst had a big 3-dimensional pore size that caused a low selectivity to bio-jet fuel production and high coke formation. Furthermore, the optimal condition for bio-jet fuel production over 10Co1Pd/HZSM-12 catalyst was found at 350 °C, 30 bar, LHSV of 1.5 h⁻¹, and H₂/feed molar ratio of 8, giving 55 % bio-jet fuel yield.

ACKNOWLEDGEMENTS

I am grateful for the full scholarship and full funding of the thesis work provided by the Petroleum and Petrochemical College and Center of Excellence on Petrochemical and Materials Technology.

This project cannot be completed without guidance and assistance from the following people.

I am deeply grateful to my advisor, Assoc. Prof. Siriporn Jongpatiwut for giving me an opportunity to do this project, giving suggestions and providing all supports until the completion of this project.

I would like to thank Prof. Thirasak Rirksomboon and Prof. Tawan Sooknoi for being my thesis committee and for giving me the suggestion for my project.

I am grateful to Global Green Chemicals Public Co., Ltd. who provides palm fatty acid distillate (PFAD) for using in this research.

I am thankful to Mr. Katipot Inkong who guides and teaches me to know about the mechanical skills for modifying the pipeline system until complete.

Moreover, I would like to thank all of my friends in Lab 604, including Titipan, Kan, Bharanabha, Chakorn, Ariya for their friendship and assistance.

Finally, I extend my gratitude to my parents for their love, support, inspiration, encouragement to me every way since I was young until I complete this project.

Jarujit Chaowichitra

CHAPTER 1

INTRODUCTION

Nowadays, transportation by airplane has been increasing due to increasing industrialization and motorization. Jet fuel, referred to as aviation fuel, is one of the major products from petroleum refinery. The combustion of fossil fuels has come into considerable attention because of the impact on environment and health, the combustion of fossil fuels has released greenhouse gases (GHG) including a myriad of toxic air pollutants and carbon dioxide (CO₂). Thus, alternative energy is necessary for solving this problem. There are many types of research attempting to develop new alternative energy for replacing the rising of petroleum-based fuel demand and the fluctuation of oil prices.

One of the most appropriate raw materials for renewable aviation fuels is the vegetable oil which contains fatty acid in the proper carbon chain range and offers a simpler approach to the production of bio-jet fuel. Palm fatty acid distillate or PFAD is a by-product from the crude palm oil refinery process that is normally used in soap and animal food industries. PFAD has become an attractive raw material since its cost is low and it does not affect to food chain. The main component in PFAD is free fatty acids which are oleic, stearic, and palmitic acids.

Bi-functional catalysts, containing metal site and acid site, comes into consideration to produce hydrocarbon in the jet fuel range (C₉ – C₁₄) from PFAD via deoxygenation process (DO) and C arrangement. In the DO process, fatty acids are transformed into saturated hydrocarbons through three possible pathways: decarboxylation, decarbonylation, and hydrodeoxygenation reactions. Then, the saturated hydrocarbons can be further converted into bio-jet fuel by hydrocracking and hydroisomerization. Pd is a noble metal highly active and selective for the DO process through decarboxylation pathway. Co is a non-noble metal which exhibits high stability and presents high performance for hydrodeoxygenation pathway at high reaction pressure. Ni is a non-noble metal selective to decarboxylation pathway and mainly taken part in hydrogenation. Therefore, side reaction such as methanation occurs which could reduce coke deposition. In addition, metals increase the acid

strength which shifts the reaction towards the hydrocracking to produce alkane which has appropriate hydrocarbons in jet fuel range. HZSM-12 is an attractive acid catalyst support because of its good stability, resistance to deposit hard coke, and excellent catalytic performance. Beside HZSM-12, HZSM-5 and HY which are commercially used as catalyst support are also studied to investigate the effect of pore size, dimensional structure, and acidity.

In this study, the conversion of PFAD to bio-jet fuels was investigated in a trickle bed reactor. The monometallic (Co and Pd) and bimetallic (CoPd and NiPd) supported on HZSM-12 zeolite with various metal loadings and bimetallic CoPd with various zeolite supports (HZSM-12, HZSM-5, and HY) were prepared by incipient wetness impregnation. The catalysts were used to investigate the conversion and products selectivity during the catalysts activity testing. The fresh catalysts were characterized by X-ray diffraction (XRD), X-ray fluorescence (XRF), Brunauer-Emmett-Teller (BET), temperature programmed reduction (TPR), temperature programmed desorption (TPD) of ammonia, and transmission electron microscopy (TEM). Furthermore, the spent catalysts were characterized by temperature programmed oxidation (TPO) and CHNS analyzer. Moreover, the optimum operating conditions (i.e. temperature, pressure, and LHSV) for producing bio-jet fuel were also investigated.

CHAPTER 2

LITERATURE REVIEW

2.1 Jet Fuel

Jet fuel is a common name for aviation fuels used in gas-turbine engine powered aircraft. Traditionally jet fuel has main components which consist of linear alkanes, branched alkanes (around 70 to 85%), and cycloalkanes. Jet fuel typically composed a carbon number in range C₉–C₁₄. Typically, jet fuel (or ‘kerosene’) corresponds to the kerosene distillation fraction of crude oil (~150 – 275 °C). Physicochemical properties of jet fuel differ from other combustion engine fuels in terms of operational conditions and engine specific technical requirements. Moreover, the relative proportion of several hydrocarbons affects the properties of jet fuel such as energy content, combustibility, density, and fluidity. Jet fuel requires the minimal composition of sulfur, oxygen, and nitrogen hetero compounds since they influence fuel stability, lubricity, corrosivity, and cooling characteristics that affect the combustion properties and the environmental impact (Kallio *et al.*, 2014). There are two main standard international specifications of aviation in the market which compose of Jet A/Jet A–1 and Jet B. Firstly, Jet A and Jet A–1 are kerosene type fuels that have the different freezing points. For Jet A, it is used in commercial flights in the United States and it has a freezing point of -40 °C or below with no additive contain while Jet A–1 have a freeze point of -47 °C or below and normally contains static dissipator additive thus it appropriate for intercontinental flights. Secondly, Jet B is jet fuel blending between naphtha and kerosene which has a low freezing point of -60 °C so it suitable for use in cold weather (Zhang *et al.*, 2016)

A strong increase in aviation transport is expected for the future as shown in Figure 2.1. It is expected that passenger transport growth of 5% per year from 2010 to 2030 and air traffic is expected to increase from 3.8% to 5.1% per year thus in 2040 RPK can reach over 18 billion PRK. For jet fuel demand, it expects to increase only 1.5% per year between 2010 and 2035 because of increasing improvements in the specific fuel (Thrän *et al.*, 2016).

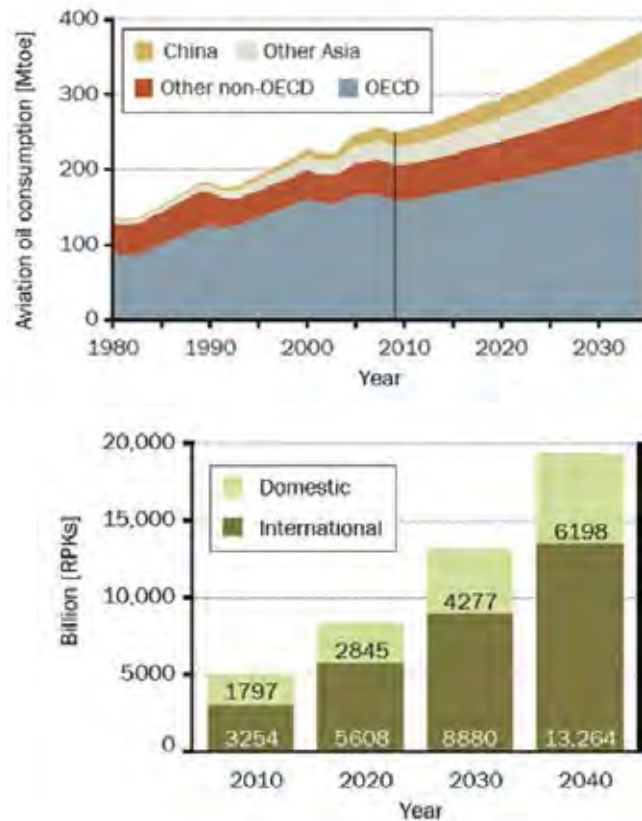

Figure 2.1 Expected growth of the aviation sector. Left: Passenger Traffic Forecast in billion revenue passengers kilometers (RPK) (most likely scenario/central forecast). Right: Aviation oil consumption [Mtoe] by region (New Policies Scenario) (Thrän et al., 2016).

Aviation transport activity and energy consumption offsetting efficiency gains of new aircraft are rapidly grown, the increase of environmental impacts must also be considered. Many greenhouse gases are released from aircraft engine and these include carbon dioxide (CO₂) and nitrogen oxides (NO_x) which have influence atmospheric chemistry and result in changes in the abundance of ozone (O₃) and methane (CH₄). CO₂ becomes the main contributor to climate change and it is included in the EU Emissions Trading Scheme (EU ETS). Airline operations worldwide produced CO₂ about 689 million tonnes and 705 million tonnes in 2012 and 2013, respectively. International Civil Aviation Organization (ICAO) (2009) forecasts that in 2050 aviation emission could be increased around 300 – 700% compared to 2005. The benefits of aviation transport will come as a cost to solve

GHG emissions. Therefore, aviation is striving to reduce the problem in the short and mid-term while at the same time they aim to find lower fuel cost burdens over the long term (Kousoulidou *et al.*, 2016).

The increase of aviation fuel application and green-house gas emissions occurred so it contributes to finding ways to solve them. The process of finding a solution includes finding alternative sustainable resources that are friendly to environmental, low cost, and reach the specific condition of jet fuel.

The increase of aviation fuel application and green-house gas emissions occurred so it contributes to finding ways to solve them. The process of finding a solution includes finding alternative sustainable resources that are friendly to environmental, low cost, and reach the specific condition of jet fuel.

2.2 Bio-jet Fuel

Biomass and liquid biofuels become attractive because of carbon neutral properties in terms of CO₂ emissions, reduced soot emissions, enhanced ignition, and it can replace the existing petroleum-derived fuels. Moreover, many sources (such as animal and plant) can use to produce liquid fuels with various properties that suitable for bio-jet fuel. (Han *et al.*, 2018)

2.2.1 Biomass-derived Aviation Fuels

Lipids are studied and used to be a feedstock for bio-jet fuel production as shown in Table 2.1. Lipids come from many raw materials such as vegetable oil, waste cooking oil, algae oil, or fermented lipids. A single step catalyst process can produce jet fuel range alkane and diesel type alkane. However, the yield of aviation fuel from common lipid which mainly C₁₈ fatty acid is low around 40 wt.%, the low yield is obstructive the use of large-scale application thus it must improve the product properties and process efficiency such as hydrocracking to convert C₁₇ and C₁₈ into aviation fuel range (C₉ – C₁₄) and avoid non-selective cracking of fatty acids. During the development of bio-aviation fuel, the control of the aromatics percentage also should be carefully considered.

Table 2.1 Recent research on the conversion of lipid to bio-aviation fuel (2010 to 2018) (Wang *et al.*, 2019)

Raw materials	Catalysts	Conversion/results/scale
Castor oil	PtAl ₂ O ₃ and Pt/ZSM-22	The castor oil to jet fuel process has a carbon selectivity of about 90% in laboratory scale experiments.
Macauba oils; almond oils	Pd/C	Hydrocarbon contents exceeded 65% in laboratory scale experiments.
Sunflower oil	ZSM-5	Yields of hydrocarbon fuels were 59.4 % – 73.9 % in laboratory scale experiments.
	BASF Nysofact 120	JP-8, naval distillate, and gasoline fractions were produced at a conservative total yield between 40 and 52 % in laboratory scale experiments.
	Sulphided NiMo and NiW supported on hierarchical mesoporous SAPO-11	Liquid hydrocarbon products were about 84 wt %, with 20 % gasoline range hydrocarbons, about 40% diesel, and about 40% aviation kerosene. Laboratory scale experiments.
Jatropha oils	Ni-W/ZSM-5	Jet-fuel range hydrocarbons were obtained at 40 – 45 %. Laboratory scale experiments.
	Ni-W/SiO ₂ - Al ₂ O ₃ ;	A Ni-Mo catalyst demonstrated the highest C ₁₅ – C ₁₈ hydrocarbon yield of about 97.9 % in laboratory scale experiments.
	Co-Mo/ Al ₂ O ₃ ; Ni-Mo/ Al ₂ O ₃	A Ni-Mo catalyst demonstrated the highest C ₁₅ – C ₁₈ hydrocarbon yield of about 97.9 % in laboratory scale experiments.

Table 2.1 (cont.) Recent research on conversion of lipid to bio-aviation fuel (2010 to 2018) (Wang *et al.*, 2019)

Raw materials	Catalysts	Conversion/results/scale
Jatropha oils	Sulfided Ni-Mo/ Al ₂ O ₃	Cracked product yield was 20 – 45% in laboratory scale experiments.
	Pt/Al ₂ O ₃ ; Rh/Al ₂ O ₃ and NiMo/Al ₂ O ₃	The highest hydrocarbon was obtained at 76.5% in laboratory scale experiments.
Microalgae oil and soybean oil	Pt/MWCNTs	The selectivity of the hydrothermal decarboxylation of stearic acid reached 97% in laboratory scale experiments.
	Pt/Al ₂ O ₃ /SAPO- 11 for HDO and Ni ₂ P/HY for hydrocracking	Fractionation resulted in 42 – 48 wt% of jet fuel with > 12% aromatics in laboratory scale experiments.
Vacuum distillate and vegetable oil mixtures	Commercial presulphided catalysts (not detailed by author)	The maximum naphtha conversion was ~65% and the highest naphtha selectivity was ~50%. Pilot scale experiments were performed.
Waste soybean oil (SBO) and palm fatty acid distillate (PFAD)	Pd/beta-zeolite catalyst	The deoxygenations of SBO and PFAD were 95.5% and 94.3%, respectively. Jet-fuel range hydrocarbons reached 69.3% in laboratory scale experiments.
Waste cooking oil	Sulfur-free Ni- Mo/ γ -Al ₂ O ₃	Hydrodeoxygenation of enzymatically pre-treated waste cooking oil achieved a yield of ~ 97% in laboratory scale experiments.

Table 2.1 (cont.) Recent research on conversion of lipid to bio-aviation fuel (2010 to 2018). (Wang *et al.*, 2019)

Raw materials	Catalysts	Conversion/results/scale
Waste cooking oil	Sulfur-free Ni-Mo/ γ -Al ₂ O ₃ Ni/Meso-Y; Ni/SAPO-34; Ni/HY	Hydrodeoxygenation of enzymatically pre-treated waste cooking oil achieved a yield of ~ 97% in laboratory scale experiments. Jet range alkanes were produced using Ni/HY, Ni/SAPO-34 and Ni/Meso-Y catalysts in laboratory scale experiments. The selectivities were 53%, 58% and 53%, respectively.
Waste soybean oil (SBO) and palm fatty acid distillate (PFAD)	Pd/beta-zeolite catalyst	The deoxygenations of SBO and PFAD were 95.5% and 94.3%, respectively. Jet-fuel range hydrocarbons reached 69.3% in laboratory scale experiments.
Waste soybean oil (SBO) and palm fatty acid distillate	Pd/beta-zeolite catalyst	The deoxygenations of SBO and PFAD were 95.5% and 94.3%, respectively. Jet-fuel reached 69.3% in laboratory scale.

2.2.2 Vegetable Oil

Nowadays, many kinds of research interests on biofuels production from several renewable feedstocks thus vegetable oil comes into attention for being feedstock. Vegetable oils with different origins have gained immense popularity as sustainable resources for biofuel production due to their high energy density and similarity in molecular structure with petroleum-based fuels. Vegetable oil has the chemical structure as shown in Figure 2.2, consisting of 98% triglycerides and other which is mono and diglycerides. Vegetable oil contains fatty acid, phospholipids,

phosphatides, carotenes, tocopherols, sulfur compounds, and traces of water (Ong *et al.*, 2011).

Figure 2.2 Typical structure of a triglyceride molecule (Ong *et al.*, 2011).

The vegetable oil commonly has fatty acids which are stearic, palmitic, oleic, linoleic, and linolenic acids. Table 2.2 shows the summary of the fatty acid composition in some common vegetable oil. Vegetable oil can be used in several paths such as straight vegetable oil, oil blends, pyrolysis, micro-emulsification, and transesterification in a diesel engine (Ong *et al.*, 2011).

Table 2.2 Chemical structure for common vegetable oil of fatty acids (Ong *et al.*, 2011)

Name	Chemical name	Structure (carbon atom : double bond)	Formula
Lauric	Dodecanoic	12:0	C ₁₂ H ₂₄ O ₂
Myristic	Tetradecanoic	14:0	C ₁₄ H ₂₈ O ₂
Palmitic	Hexadecanoic	16:0	C ₁₆ H ₃₂ O ₂
Stearic	Octadecanoic	18:0	C ₁₈ H ₃₆ O ₂
Oleic	cis-9-Octadecenoic	18:1	C ₁₈ H ₃₄ O ₂

Table 2.2 (cont.) Chemical structure for common vegetable oil of fatty acids (Ong et al., 2011)

Name	Chemical name	Structure (carbon atom : double bond)	Formula
Linoleic	cis-9,cis-12- Octadecadienoic	18:2	C ₁₈ H ₃₂ O ₂
Linolenic	cis-9,cis-12,cis-15- Octadecatrienoic	18:3	C ₁₈ H ₃₀ O ₂
Arachidic	Eicosanoic	20:0	C ₂₀ H ₄₀ O ₂
Gadoleic	11-eicosenoic	20:1	C ₂₀ H ₃₈ O ₂
Behenic	Docosanoic	22:0	C ₂₂ H ₄₄ O ₂
Erucle	cis-13-Docosenoic	22:1	C ₂₂ H ₄₂ O ₂
Lignoceric	Tetracosanoic	24:0	C ₂₄ H ₄₈ O ₂

2.3 Palm Fatty Acid Distillate Feedstock

Palm oil is a tropical plant that grows in lowland with humidity as shown in Figure 2.3. The fruit consists of a fibrous mesocarp layer and the endocarp (shell) containing the kernel which contains oil and carbohydrate reserves for the embryo as shown in Figure 2.4. Palm oil is used mainly in food application and this edible oil production comes into attention for feedstock. The palm oil processing industry began in Malaysia around the 1970s and then used in the processes of refining and fractionation, alone or in combination (Ong *et al.*, 2011).

Figure 2.3 Oil palm tree and fruits (Ong *et al.*, 2011).

Figure 2.4 Fresh oil palm fruit and its longitudinal section (Ong *et al.*, 2011).

Production oil yield for various sources of biodiesel feedstock as shown in Figure 2.5. soybean, palm, sunflower, rapeseed and peanut oil are considered as an alternative fuel for the diesel engine. Moreover, many interesting alternative fuels come into attention such as mustard seed, *Jatropha curcas*, cottonseed, and *Calophyllum inophyllum* oil. They can drive in current situations which have an increasing population, rising standards of living, and increasing incomes in developing countries. From all of this, palm oil gives high potential products, high production rates, and high oil content that have ability to meet the future demand. As shown in Figure 2.5, oil palm gives high potential productivity of 5,950 liters per hectare which is 13 times higher than soybean oil and the following high oil productivity is *Calophyllum inophyllum* oil. Life cycle analysis (LCA) conducted on various biodiesels and the result showed that palm oil-based biodiesel can reduce

greenhouse gases (GHG) emission by 62% as compared to soybean oil (40%), rapeseed oil (45%) and sunflower oil (58%).

Figure 2.5 Production oil yield for various sources of biodiesel feedstock (Ong *et al.*, 2011).

In these few decades, global demand for edible oil is increasing and there causes a high rate of increase in the area of oil crop cultivation especially soybean and oil palm. The world production of palm oil is 45 million tonnes and the highest production is in South East Asia with a total of 89% of total palm oil production which consists of 40% in Malaysia, 46% in Indonesia, 3% in Thailand as shown in Figure 2.6. The highest land using for oil palm cultivation is Malaysia about 4.5 million hectares. It produced 17.73 million tonnes of palm oil and contributed about 65.19 billion to the Malaysia export in 2008. Malaysia has approximately 362 palm oil mills and processing 71.3 million tonnes of fresh fruit bunch. Moreover, producing an estimated 19 million tonnes of crop residue annually in the form of empty fruit fiber, bunch, and shell. Table 2.3 shows oil palm biomass components, quantity, calorific values, and moisture content that can be used for electricity. Palm oil is one of the most efficient oil because of land utilization, efficiency, and productivity (Ong *et al.*, 2011).

Figure 2.6 World palm oil production 2009 (Ong *et al.*, 2011).

Table 2.3 Oil palm biomass components and potential energy generated (Ong *et al.*, 2011)

Oil palm component	Quantity (million tonnes)	Calorific value (kJ/kg)	Potential energy generated (Mtoe)
Empty fruit bunch	17.00	18,838	7.65
Mesocarp fibre	9.6	19,096	4.37
Shell	5.92	20,108	2.84
Palm kernel	2.11	18,900	0.95
Total	34.63		15.81

The crude palm oil (CPO) is physically refined by removing impurities to reach acceptable levels. The refinery process of palm oil was shown in Figure 2.7. Firstly, the process removes an impurity called gum (phospholipids, phosphatides) in crude palm oil by precipitation process. The appropriate temperature for precipitation usually occurs at 90 – 130 °C and uses phosphoric acid as a precipitant. Then, CPO goes to the degummed palm oil (DPO) process. The degummed palm oil is bleached

for removing any undesirable impurities such as pigments and trace metals. The output of this process is bleached palm oil (BPO). Next, BPO is deodorized to eliminate free fatty acid content. This step including refined, bleached, and deodorized palm oil (RBDPO) gives palm fatty acid distillate (PFAD) as a by-product. Finally, the RBDPO is fractionated to give refined palm olein (RPO) and refined palm Stearin (RPS) (Kiatkittipong *et al.*, 2013).

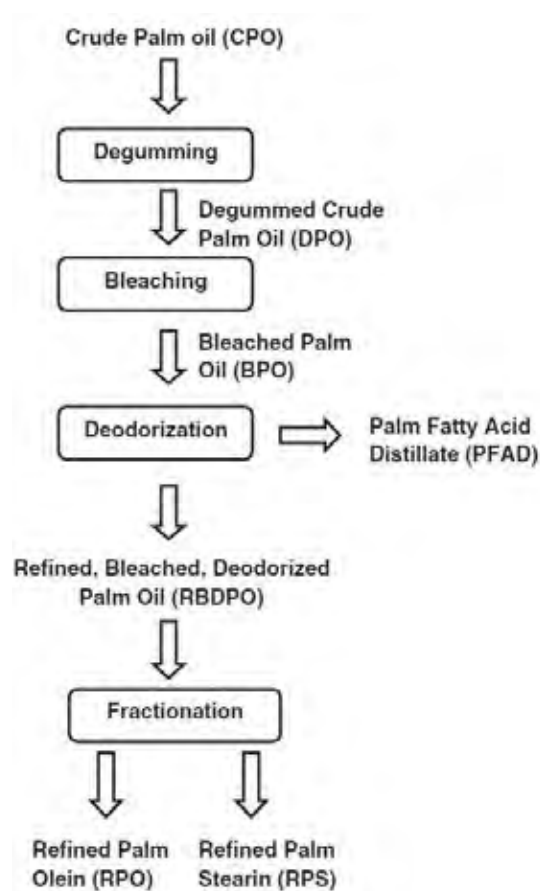

Figure 2.7 Physical refining process of crude palm oil (Kiatkittipong *et al.*, 2013).

Palm fatty acid distillation or PFAD is a by-product of crude palm oil production. PFAD has a highly odoriferous product that also contains a minor component of glycerol esters with the feedstocks. PFAD has a light brown solid at room temperature and melting to a brown liquid on heating about 83 °C. It is no official production data on PFAD to be available unlike the crude palm oil and

processed palm oil products, but PFAD has estimated information of volume and values that are given in Table 2.4.

Table 2.4 Refining volumes (tonnes) and value of palm oil & PFAD in Malaysia. 2012 – 2015 average (Ab Gapor Md, 2010)

	Refining output	Value (theoretical)
Refined, Bleached and Deodorised Palm Oil	13,966,000 ton	\$10,810,000,000
PFAD	678,000 ton	\$445,000,000

2.4 The Overall Reaction for Bio-jet Fuel Production

2.4.1 Deoxygenation Reaction

The deoxygenation method converts fatty acid to produce linear long chain hydrocarbon in the presence of both H₂ and H₂-free environments. During the catalytic deoxygenation process, oxygen is removed from fatty acid to get pure hydrocarbon fuels that are fully compatible with diesel. Deoxygenation process has three possible pathways which consist of decarboxylation (DCX), decarbonylation (DCN), and hydrodeoxygenation (HDO) reactions, where the H₂ consumption for the reaction follows the order of DCX < DCN < HDO. Decarboxylation and decarbonylation in liquid phase produce gas phase CO₂, CO, H₂, and H₂O which can further occur water-gas-shift reaction and methanation of CO₂ and CO. A detailed scheme for various deoxygenation pathways along with other possible reactions like the water-gas-shift reaction and hydrogenation occurring in the process is shown in Figure 2.8 (Pattanaik *et al.*, 2017).

Figure 2.8 Various deoxygenation reaction schemes with other possible reactions including thermodynamic data (ΔG_{573} in kJ/mol at 1 bar) (Pattanaik et al., 2017).

2.4.1.1 Decarbonylation (DCN)

Decarbonylation (DCN) refers to the removal of the carbonyl group in less H_2 environment to produce alkanes with one carbon lesser than the original fatty acid.

2.4.1.2 Decarboxylation (DCX)

Decarboxylation (DCX) refers to the removal of the carboxyl group from fatty acid to produce alkanes by the direct attack at C – C bond with no H_2 environment and high reaction temperature.

2.4.1.3 Hydrodeoxygenation (HDO)

Hydrodeoxygenation is an oxygen displacement process that depends on the use of pure hydrogen H_2 under specific temperature and high-pressure condition for direct scission of C–O bond, fatty acids are converted to saturated hydrocarbon and O_2 is removed in the form of water.

2.4.2 Methanation and Water-Gas-Shift Reactions

CO₂ methanation reaction can occur during deoxygenation reaction as the joining of two reactions: water-gas-shift reaction and CO methanation. The main gaseous products from the deoxygenation reaction of triglyceride-based vegetable oil are CO₂, CO, H₂, and C₃H₈. It is generally observed that the decarbonylation /decarboxylation pathway consumes less H₂ and produces C₁₅ and C₁₇ hydrocarbons. However, hydrodeoxygenation has higher hydrogen consumption which needs specific temperature and pressure and gives C₁₆ and C₁₈ hydrocarbons products. For decarboxylation reaction, the reaction releases more CO₂ as a by-product. After CO₂ reacts with four molecules of H₂, it will give methanation reaction and produces CH₄ with two H₂O molecules. Similarly, CO and three H₂ molecules react together, they form CH₄ and two molecules of H₂O. Furthermore, this reaction leads to the formation of lighter products. In addition, when CO and H₂O go through water-gas-shift reaction, CO₂ and H₂ are formed as shown in Table 2.5 and Figure 2.9 (Khan *et al.*, 2019).

Table 2.5 Methanation and water-gas-shift reactions (Feng *et al.*, 2019)

Reaction No.	Reaction formula	ΔH_{298K} (kJ/mol)	Reaction type
1)	$\text{CO}_2 + 4\text{H}_2 \leftrightarrow \text{CH}_4 + 2\text{H}_2\text{O}$	-165	Methanation reaction
2)	$\text{CO} + 3\text{H}_2 \leftrightarrow \text{CH}_4 + \text{H}_2\text{O}$	-206	Methanation reaction
3)	$\text{CO} + \text{H}_2\text{O} \leftrightarrow \text{CO}_2 + \text{H}_2$	-42	Water-gas-shift reaction

Figure 2.9 Methanation and water-gas-shift reactions (Khan *et al.*, 2019).

2.4.3 Hydrocracking and Isomerization Reactions

The deoxygenation process (DO) can be improved by adding more reactions. It usually produces alkane which gives a high cetane number. However, issues are occurred by these paraffin oils from their poor cold flow properties. Therefore, improving their physiochemical properties by hydrocracking and isomerization come into attention. Hydrocracking of alkanes is useful for the industrial process which is developed by petroleum refineries for producing gas hydrocarbons, gasoline, and kerosene from heavy fractions. Cracking reaction produces straight chain alkanes (C_{15} above) which need further cracking to be a suitable jet fuel range. After hydrocracking, normal long chain paraffins are converted to range C_9 to C_{14} hydrocarbon chains which are more suitable for jet fuel application. After hydroisomerization, the alkanes are maintained the high cetane number and improve the cold flow properties, the isomerization process converts *n*-paraffins or straight-chain hydrocarbons into iso-paraffin or branched structures to reduce the freezing point in order to meet the jet fuel specification and standard. The hydrocracking and isomerization reactions can be performed either together or respectively for the formation of hydrocarbons. Wei *et al.* suggested that hydrocracking is an important process before isomerization reaction to give a lighter alkane (Khan *et al.*, 2019).

There are several previous researches interesting to use vegetable as a feedstock for producing bio-jet fuel by the various metal catalyst.

De Sousa *et al.*, 2016 used palm kernel oil (palmist oil) to produce bio-hydrocarbons in hydrocarbon range of diesel and jet fuel via hydrodeoxygenation and its hydrolyzed product by using Pd/C as a catalyst. It gave hydrodeoxygenation with conversion of up to 96% at 10 bar of H₂ pressure and 300 °C.

Lai *et al.*, 2016 reported that the formation of Pd and Pt overlayer on Ni base metal would cause a negative shift of the d-band center of surface Pd or Pt and result in reducing the binding strength for adsorbed species. The resulting Pd and Pt active sites of overlayer catalysts significantly enhanced deoxygenation activity compared with that of Pd or Pt only catalysts.

Choi *et al.* 2018 showed that the bimetallic WO_x/Pt/TiO₂ catalyst enhances the performance of deoxygenation reaction. Bio-jet fuel range alkanes were prepared by using non-edible acid oils as a feedstock. For only WO_x metal or Pt metal on TiO₂ support had a low activity to deoxygenation reaction. Otherwise, WO_x addition to Pt/TiO₂ enhanced performance which gave a degree of deoxygenation of 86% C₁₇ carbon selectivity which is more than two times higher than the Pt/TiO₂.

Thongkumkoon *et al.* 2019 presented trimetallic ReNiMo sulfide supported on γ -Al₂O₃ toward the deoxygenation of oleic acid, palm fatty acid distillate (PFAD), refined palm stearin (RPS) and refined palm olein (RPO). They found that using trimetallic catalysts had the highest diesel yield of 76.5% from oleic acid, 72.5% from PFAD, 69.7% from RPS, and 69.5% from RPO when compare to nanocatalyst. Moreover, adding some metal can promote characterization of catalyst like additional of Re increased the NiMo surface area by 20.4% and it reduced the metal particle size and gave high the metal dispersion on the support.

Hengsawad *et al.* 2018 studied the uses of Pd supported TiO₂ and Pd supported activated carbon catalysts for deoxygenation of triglycerides. They studied two different types of titania supports compose of mesoporous titania synthesized by a surfactant-assisted templating sol-gel method (SG-TiO₂) and commercial P25-TiO₂. It found that using TiO₂ support exhibited higher catalyst performance compare to

active carbon due to SMSI effect. SMSI effect give defect (oxygen vacancies and Ti^{3+}) on TiO_2 . Furthermore, single-step sol-gel (SSSG) showed the highest conversion and selectivity to the diesel fuel ($\text{C}_{15} - \text{C}_{18}$) because of the well dispersion of Pd metal catalyst in support.

Zhang *et al.*, 2016 studied Pd-Ni/HZSM-5 catalyst for Tandem Limonene dehydrogenation. The process involves the formation of *p*-cymene with generate H_2 as a by-product. Afterward, H_2 from the previous reaction is used for hydrodeoxygenation of stearic acid under low H_2 pressure (2 bar) to produce C_{17} and C_{18} alkane. The heterogeneous 5%Pd-10%Ni/HZSM-5 catalyst at 300 °C is effective for the full conversion of stearic acid and limonene via a cascade reaction sequence. In addition, the main route of limonene conversion is carbonylation reaction which leads to long-chain carbon 17 alkane formation and gas phase that present is H_2 , CO , and CH_4 . The process also occurred CO_2 methanation that reduces CO_2 in process.

Ameen *et al.*, 2019 studied between non-sulphided monometallic Ni/ γ - Al_2O_3 and Mo/ γ - Al_2O_3 catalysts by conventional wet impregnation method to produce automotive clean fuel production via hydrodeoxygenation of rubber seed. They used 3 wt.%, 12 wt.%, and 15 wt.% Ni and Mo loading over γ - Al_2O_3 support. The result showed that the highest both Ni and Mo gave the highest yield. Moreover, nickel support had a higher surface area, small particle size, homogeneous dispersion of particles, higher crystallinity, lower reduction temperature, and low coke deposition due to CO_2 methanation appearance. The reaction mainly in decarboxylation (DCO_2) reaction. Otherwise, Mo loading enhanced hydrodeoxygenation reaction and gave a higher yield than Ni loading although it exhibited a high amount of coke deposition when compared to Ni supports catalyst.

2.5 The Catalyst for Bio-jet Fuel Production

The metal/acid bi-functional catalyst comes into attention for converting PFAD to high quality hydrocarbons in jet fuel range. The acid zeolite support with different porosity is an important effect on reaction activity and stability.

2.5.1 Zeolite as a Support Catalyst for Biojet Fuel Production

Zeolites are microporous crystalline aluminosilicates which have a high regular and open microporous (< 2 nm) structure. This structure is formed by a three-dimensional network of SiO_4 and AlO_4^- tetrahedral. The tetrahedral are linked to each other by shared oxygen atoms, to give cavities or cages, which are connected by ring or pore openings, with defined size and shape (Figure 2.10). There are several zeolites supports with different topology, channel structure, and pore size for various catalytic performance as shown in Table 2.6 (Ramsay *et al.*, 2000).

Figure 2.10 Composition of zeolites: from primary building unit to zeolite cage-like frameworks (Ramsay *et al.*, 2000).

Table 2.6 The topology, channel structure, size, and pore model of zeolites (Zhang *et al.*, 2016)

Material	Topology	Channel structure	Channel size	Pore model
ZSM-48	MRE	1D, 10-R	5.6 x 5.3 Å	Unimicro-pore
ZSM-12	MTW	1D, 12-R	5.6 x 6.0 Å	Unimicro-pore
ZSM-22	TON	1D, 10-R	5.7 x 4.6 Å	Unimicro-pore
ZSM-23	MTT	1D, 10-R	3.6 x 4.8 Å	Unimicro-pore
SAPO-11	AEL	1D, 10-R	4.3 x 7.0 Å	Unimicro-pore
SAPO-41	AFO	1D, 10-R	4.0 x 6.5 Å	Unimicro-pore
SAPO-35	LEV	2D, 8-R	3.6 x 4.8 Å	Unimicro-pore
SAPO-34	CHA	3D, 8-R	5.3 x 5.4 Å	Unimicro-pore
HY	FAU	3D, 12-R	7.4 x 7.4 Å	Unimicro-pore
ZSM-5	MFI	3D, 10-R	5.1 x 5.5 Å	Unimicro-pore

Zeolites are widespread applications in the petrochemical industry such as fluid catalytic cracking (FCC), aromatics conversion, and olefin production. There are more than two hundred zeolite frameworks have been defined and announced by the International zeolite association. The zeolite frameworks are described by using a three-letter code. However, even the natural zeolite is important for industrially applied zeo-catalysts in oil refining and the petrochemical process is still placed on zeolites Y (FAU), ZSM-5 (MFI), mordenite (MOR), beta (BEA), MCM-22 (MWW) and zeolite-like SAPO-34 (CHA), etc. The reason is their unique pore architectures that provide a perfect match with the requirement of target reactions, and their possessing suitable accessibility of active sites for guest molecules (Shi *et al.*, 2015).

Zeolites have the chemical composition: $M_{x/n}[(AlO_2)_x(SiO_2)_y] \cdot ZH_2O$ where x and y are integers, y/x equal to or greater than 1, n is the valency of cation M and Z is the number of water molecules in each unit cell. M is an extra-framework cation that balances the anionic charge of the framework. The Si/Al is an atomic ratio or molar ratio varies between 1 to ∞ ($M = SiO_2/Al_2O_3$). Zeolite can be occurred by nature and synthesis. Zeolite catalysts have various catalysis abilities because of their chemical composition, pore size distribution, and ion-exchange abilities. Furthermore, zeolite catalysts have both acidic and basic characteristics.

Zeolites are inexpensive and environmentally friendly, so they are widely used as heterogeneous catalysts in the industry. Generally, there are three types of zeolites, depending on their pore volume. There are small pore zeolites which have a diameter between 2.8 – 4 Å and containing rings with 6 – 8 members such as Sodalite and zeolite A, medium-pore zeolites which have diameter 5 – 6 Å and containing 10 membered rings (ZSM-type zeolites) and large-pore zeolites which have diameter more than 7 Å and constructed with 12 membered rings such as zeolites X and Y and faujasite-type zeolites (Shahinuzzaman *et al.*, 2017)

The several types of zeolite supports have been studied in isomerization. One-dimensional structures such as ZSM-22, ZSM23, and SAPO-11 revealed shape selectivity while 12 membered rings such as ZSM-12, Beta, and USY are devoid shape selectivity and facilitated the formation of multi-branched isomers. The 10 membered rings zeolites have high shape selective called pore mouth selectivity which long chain hydrocarbon cannot diffuse inside the pore, leading to mono-branched products. The yield of multibranched isomers C10 is shown as a function of mono-brance C10 in Figure 2.11.

The optimal acidity linked to the occurrence of both isomerization and hydrocracking on Bronsted acid sites. More acidic catalyst has a trend to excessively cracking whereas less acidity allows only weak isomerization, resulting in low octane number. The acidity of zeolite can be adjusted by the SiO_2/Al_2O_3 ratio

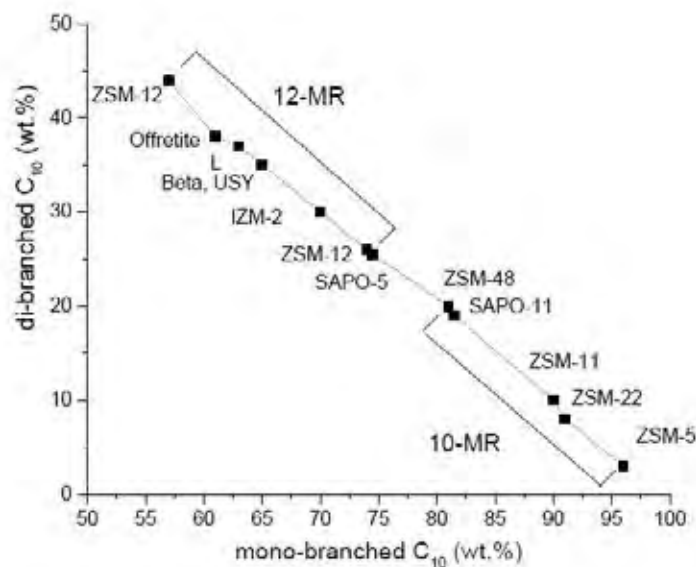

Figure 2.11 The yield of di-branched C10 as a function of monobranched C10 in n-decane hydroisomerization at 5% isomerization yield. Conditions: 4.5 bar, 300 °C, H₂/n-C₁₀ molar ratio of 214, WHSV of 0.37 h⁻¹ (Mäki-Arvela et al., 2018).

Ju *et al.*, 2016 integrates hydrotreating process and hydroisomerization to achieve the main specification requirement of jet fuel production through HEFA route. The results show that Pt/ZSM-12 has efficient converting *n*-C₁₅ paraffin into multi-branched isomer and mono branched isomer with high weight yield 60% of algal oil to jet fuel rather than ZSM-22 and USY catalyst. Moreover, it gives a high multi/mono-isomers ratio which is satisfied with the ASTM specification of aviation biofuel. In addition, Marcelo *et al.*, 2015 showed the result of HZSM-12 zeolite (Si/Al = 40), it was active in *n*-heptane catalytic cracking to C₁ to C₆ production. HZSM-12 with one dimensional and 12-member-ring channel system is interesting for application in several reactions of industrial interest due to its good stability, resistance to deposition of hard coke, and excellent performance in catalytic processes.

As-synthesized HZSM-5 zeolites with different Si/Al ratios including 25, 90, 120, 240, and 400 used for dehydration of methanol to dimethyl ether (DME), which is a promising gaseous automotive fuel in the future. It was found that the Si/Al ratio of HZSM-5 had considerable impacts on its catalytic performance for

dehydration of methanol to DME and acidity increased with decreasing Si/Al ratio from 400 to 25 (Sameh *et al.*, 2017).

2.5.2 Active Metal and Promoter

Support group VIII noble metal over support significantly affects on several deoxygenation reactions. Support group VIII noble metal is like a guide to what the reaction will be like. Thus, Pd catalyst comes into interest because proceeds mainly react via decarbonylation (DCN) and decarboxylation (DCX) pathways. Both pathways are favorable in terms of economic assessment. Pd/C catalyst shows completely converting steric acid to deoxygenated C₁₇ products with high selectivity (98%) Moreover, The study found that activities for the deoxygenation of metals incorporated on the same support increased in the order of Os < Ru < Ir < Rh < Ni < Pt < Pd (Snåre *et al.*, 2006).

Cobalt is a very active non noble metal in deoxygenation reaction which mainly follows the hydrodeoxygenation reaction pathway at high reaction pressure. On the other hand, Cobalt has ability to go through decabonylation pathway at lower pressure. Cobalt loading is not only enhancing the deoxygenation but also shift the reaction towards the hydrocracking process to produce bio-jet fuel due to cobalt gives acid strength and amount acid site for cracking. Moreover, cobalt exhibits stability for the reaction without deactivation. (Cao *et al.*, 2018). Moreover, Srifa *et al.*, 2015 also investigated the effect of Co with Ni, Pd, and Pt on alumina support for converting vegetable oil to replace petroleum diesel via deoxygenation reaction. The reaction tests show that the catalytic activity was in the order of Co > Pd > Pt > Ni respectively. Ni, Pd, and Pt catalysts gave more dominant in decarbonylation reaction whereas Co catalyst give hydrodeoxygenation reaction with occurred light hydrocarbon since the Co was partially selective to C–C cleavage in hydrocarbon chain.

CHAPTER 3

EXPERIMENTAL

3.1 Materials and Equipment

Material:

Feedstock

- Palm fatty acid distillate (obtained from Global Green Chemicals Public Co., Ltd., Thailand)

Chemical

- LUDOX HS-40 colloidal silica (40 wt.%, Dupont)
- Sodium aluminum oxide (Technical grade, Alfa Aesar)
- Tetraethylammonium hydroxide solution (TEAOH, 40 wt.% in water, Fluka)
- Palladium (II) chloride ReagentPlus (PdCl₂, 99% purity, Sigma Aldrich)
- Nickel nitrate hexahydrate (NiNO₃.6H₂O, Sigma Aldrich)
- Cobalt (II) nitrate hexahydrate (Co(NO₃)₂.6H₂O, Sigma Aldrich)
- Hydrochloric acid (HCl, 37 wt %, Emsure)
- Ammonium nitrate (NH₄NO₃, Ajex Finechem)
- HY zeolite (SiO₂/Al₂O₃ ratio of 100, Tosoh Company)
- ZSM-5 zeolite (SiO₂/Al₂O₃ ratio of 50, Zeolyst International Company)
- Dichloromethane (CH₂Cl₂, Honeywell)
- Pyridine (C₅H₅N, 98 % purity, Carlo Erba)
- N,O-bis(trimethylsilyl)-trifluoro acetamide (BSTFA, C₈H₁₈F₃NOSi₂, 99 % purity, Sigma Aldrich)
- Eicosane (C₂₀H₄₂, 99 % purity, Sigma Aldrich)
- Methanol (CH₃OH, 99.9 % purity, CT Chemical)
- Acetone (CH₃COCH₃, 99.5 % purity, CT Chemical)
- Hexane (C₆H₁₄, 99.9 % purity, CT Chemical)
- Deionized water

Gases

- Hydrogen (H₂, HP grade, 99.99 % purity)
- Helium (He, UHP grade, 99.999 % purity)
- Nitrogen (N₂, HP grade, 99.99 % purity)
- Air zero (HP grade, 99.99 % purity)

Equipment:

1. High pressure packed-bed continuous flow reactor system
2. Mass flow controller (Brooks instrument 5850E)
3. Teledyne ISCO syringe pumps 1000D
4. Back pressure regulator (Siemens)
5. ¾" O.D.x16" long stainless-steel reactor
6. Three-zone tubular furnace with a temperature controller (Cabolite)
7. Gas chromatograph (Agilent GC 7890 equipped with injector, DB-5HT column and FID)
8. Gas chromatograph (Hewlett Packard 5890 series II, HP-PLOT/Al₂O₃ column)
9. Chamber Furnace (Cabolite)
10. X-ray diffractometer (XRD)
11. Transmission electron microscopy (TEM)
12. Surface area analyzer (AS-3XR)
13. Temperature programmed reduction (TPR) apparatus
14. Temperature programmed desorption (TPD) apparatus
15. Temperature programmed oxidation (TPO) apparatus
16. CHNS analyzer (LECO / Truspec CHN/S)
17. X-Ray fluorescence spectrometer (WDXRF)
18. Hot & stirrer plate (Cole Parmer)
19. Wet test gas meter (Ritter)

3.2 Experimental Procedures

3.2.1 Catalyst Preparation

3.2.1.1 *Synthesis of ZSM-12 Catalyst*

The parent ZSM-12 ($\text{SiO}_2/\text{Al}_2\text{O}_3$ ratio of 100) was synthesized from hydrogel solutions with the following molar composition $100\text{SiO}_2: 1\text{Al}_2\text{O}_3: 1\text{Na}_2\text{O}: 25\text{TEAOH}: 1500\text{H}_2\text{O}$ (Fang *et al.*, 2008). TEAOH was mixed with deionized water and sodium aluminum oxide until the solid dissolved then added Ludox in solution and stirred at 250 rpm for 24 h until the gel became uniform. Next, the resultant gel was transferred to a 100 mL Teflon-lined stainless-steel autoclave and crystallized by thermal treatment under autogenous pressure and static conditions at 160 °C for 120 h (5 days). After hydrothermal synthesis, the autoclave was removed and cooled down to room temperature then recovered product by filtration with deionize water around 1500 mL. After that, product was dried at 120 °C overnight and removed the organic template by calcining in air flow at 550 °C for 5 h with a heating rate of 10 °C/min.

3.2.1.2 *Treatment of ZSM-12 with Ammonium Nitrate*

After the first calcination, the as-synthesized ZSM-12 was ion-exchanged with a 100 mL of 1 molar ammonium nitrate solution for three times at 80 °C, then washed with deionized water to remove the nitrate ions. Zeolite was dried at 120 °C overnight and calcined in air at 550 °C for 5 h with heating rate of 10 °C/min to obtain HZSM-12 (acidic form).

3.2.1.3 *Preparation of HZSM-5 and HY Catalysts*

The ZSM-5 and Y zeolite catalysts were dried at 120 °C overnight then the dried catalysts were calcined in air flow at 550 °C for 5 h with heating rate of 10 °C/min for removing impurity and obtaining H^+ form (HZSM-5 and HY) (Li *et al.*, 2016).

3.2.2 Metal Loading on Zeolite Supports

The metals were loaded in zeolite supports by incipient wetness impregnation method. PdCl₂ was firstly dissolved in HCl solution at 80 °C to afford H₂PdCl₄ solution. For Co metal loading, Co(NO₃)₂·6H₂O was firstly dissolved in water. The Pd and Co precursors were mixed and slowly dropped onto zeolite support, then the catalyst was dried at 80 °C overnight. The dried catalyst was calcined in an air flow at 500 °C for 6 h with a heating rate of 2 °C/min.

3.3 Catalyst Characterizations

3.3.1 X-ray Diffraction (XRD)

X-ray diffraction was used to determine the information of the crystalline phase of ZSM-12 synthesized catalyst before and after metal incorporation by a Rigaku X-ray diffractometer with Cu tube for generating CuK_α radiation (1.5406 Å) at room temperature. The sample was measured in the 2θ range of 5–50° with a scanning rate of 5°/min and a step of 0.02°.

3.3.2 X-ray Fluorescence (XRF)

X-ray fluorescence spectrometer (WDXRF) was used to determine its chemical or elemental composition. An X-ray beam with enough energy interacted with the atom by replacing electron from inner shell. Atom became unstable from missing inner electron then an outer electron replaced the missing inner electron. The replacement occurred the difference energy between the X-ray beam from analyzer and the binding energy that held electrons in their proper orbits.

3.3.3 Surface Analysis

Autosorb-1MP (AS-3XR) surface analyzer was used to measure surface properties of the prepared catalysts. Firstly, the sample was outgassed to remove humidity and volatile adsorbents adsorbed on the surface under vacuum at 250 °C for 10 h before the analysis. Then, N₂ was purged to adsorb on the surface then the quantity of gas adsorbed or desorbed from their solid surface was observed by static volumetric method at equilibrium vapor pressure. The solid sample was maintained at a constant temperature of the sample cell until the equilibrium was

established. This volume-pressure data would be used to calculate the BET surface area.

3.3.4 Temperature Programmed Reduction (TPR)

The reducibility of the catalysts was analyzed by a temperature-programmed reduction (H₂-TPR) under a reducing gas consists of 5% H₂ in N₂ with a thermal conductivity detector. Firstly, the calcined catalyst was dried at 120 °C overnight, then 0.1 g catalyst was packed inside a 1/4" O.D. quartz tubular reactor between the layers of quartz wools. After that, the sample would be exposed to a stream of 5% H₂ in N₂ with 30 mL/min then the sample was heated to 800 °C with a heating rate of 10 °C/min. The H₂ consumption was monitored and collected by an SRI model 110 TCD detector as a function of temperature.

3.3.5 Temperature Programmed Desorption (TPD)

The Thermo Finnigan temperature programmed desorption/reduction/oxidation analyzer (TPDRO/TF) was used to analyze the acidity of the prepared catalysts. Initially, 0.2 g of sample was pretreated with nitrogen at 300 °C for 1h and adsorption ammonia at 100 °C for 1 h, then cooled down to 50 °C. After the pretreatment, the sample was heated in a flow of 30 mL/min helium to 900 °C with a heating rate of 10 °C/min and hold for 2 h then cooled down the catalyst. The desorbed ammonia was analyzed online using a TCD detector.

3.3.6 Transmission Electron Microscopy (TEM)

Transmission electron microscopy (JEM-1400) was used to observe the morphology of preparing catalysts. The catalyst was prepared by dispersing on the carbon film coating TEM grid then it was suspended in isopropanol solvent. After that, the sample was sonicated and dried overnight at room temperature.

3.3.7 Temperature Programmed Oxidation (TPO)

The Thermo Finnigan temperature programmed desorption/reduction/oxidation analyzer (TPDRO/TF) was used to analyze coke of spent catalysts. Initially, 0.1 g of the sample was pretreatment with nitrogen at 250 °C and held for 30 min. After pretreatment, the sample was heated with a flow of 30 mL/min 5.27% oxygen in helium to 800 °C with a heating rate of 10 °C/min and hold for 2 h then cool down the

catalyst. The CO_x products from the oxidation were measured online using a TCD detector.

3.3.8 CHNS Analyzer

Leco CHNS analyzer was used to determine the amount of carbon by the combustion of sample in high temperature furnace with an infrared detector. The analyzer was heated to 950 °C and held for 4 h. Blank test and EDTA standard were performed to calibrate the instrument. After that, 0.2 g of sample was wrapped with tin foil and loaded in the machine. The combustion products were analyzed by infrared detection to determine carbon contents.

3.4 Catalytic Activity Testing

The schematic of the reactor system and the description of flow-diagram are shown in Figure 3.1 and Table 3.1. The reactions (i.e. hydrodeoxygenation, decarbonylation, decarboxylation, isomerization, and hydrocracking) were carried in a 3/4" O.D. stainless steel trickle-bed reactor. Firstly, the catalyst was reduced under pressure H₂ for 3 h at the reduction temperature of catalyst. Then, the temperature and pressure were set to the desired reduction temperature. After that, the PFAD stream was fed into the reactor by a Teledyne 1000D Isco syringe pump.

Mass flow controller and back-pressure regulator used for controlling the flow of carrier gas and the reaction pressure, respectively. During the process, the liquid product was trapped and collected in a condenser while the gas product was analyzed by using a Hewlett Packard 5890 series II gas chromatograph equipped with a capillary HP-PLOT/Al₂O₃ "S" deactivated column and FID detector. In addition, the amount of gas product was determined by a wet test gas meter (Ritter TG 05/2). Finally, the liquid product was analyzed by another gas chromatograph, Agilent 7890 equipped with a DB-5HT column and FID detector. Both gas and liquid product were collected and analyzed hourly.

Figure 3.1 The schematic diagram of the reactor system.

Table 3.1 The description of system in flow diagram of the continuous flow trickle-bed reactor

No.	Part	Description
1	V1	On-off valve for feedstock from ISCO syringe pumps
2	V2	On-off valve for avoiding the backward flow of the feedstock
3	V3	Three ways valve for switching between gas flow meter controller and bypass
4	V4	Needle valve for releasing gas from bypass
5	V5	Three ways valve for switching between nitrogen gas and hydrogen gas flow
6	V6	Three ways valve for switching between vent gas and gas to GC lines
7	V7	Needle valve for gathering the liquid product from condenser
8	V8	On-off valve for collecting liquid product
9	R1	Continuous flow trickle-bed reactor where hydroprocessing reaction take place

Table 3.1 (cont.) The description of system in flow diagram of the continuous flow trickle-bed reactor

No.	Part	Description
10	FC	Flow controller to set flow rate for the desired H ₂ /feed molar ratio
11	PG	Pressure gauge for indicating pressure in packed bed reactor
12	PC	Back pressure regulator for controlling the pressure in reactor

The hydroprocessing reaction of PFAD was performed at temperature, pressure, liquid hourly space velocity (LHSV), and H₂/PFAD molar ratio as shown in Table 3.2.

Table 3.2 The reaction conditions for hydroprocessing of PFAD in continuous flow trickle-bed reactor

Parameter	Value
Reaction Temperature (°C)	325 – 375
Reaction Pressure (bar)	10 – 30
LHSV (h ⁻¹)	1.5 – 2.5
Volume of Catalyst (mL)	4
Particle Size of Catalysts (mesh)	20 – 40
H ₂ /feed Molar Ratio	8

3.5 Product Analysis

3.5.1 Liquid Products Analysis

Gas chromatograph (Agilent 7890) equipped with FID detector was used to measure liquid product. Non-polar hydrocarbons liquid product from the hydrocracking of PFAD were determined by using a DB-5 column (non-polar column).

The GC operating condition was summarized as follows:

Injector temperature : 50 °C

Detector temperature : 380 °C

Carrier gas : He

Column type : Capillary column

(DB-5HT diameter 0.32 mm length 30 m)

The following chromatographic temperature program in Table 3.3 was used for liquid product analysis:

Table 3.3 The chromatographic temperature program for liquid product analysis

Step	Temperature (°C)	Rate (°C/min)	Holding time (min)
1	50	-	5
2	169	10	10
3	380	20	10

For the weight of the liquid product, the areas of each peak were analyzed hourly by a GC/FID (Agilent 7890) and were converted to gram unit by Equation 3.1.

$$\text{Weight of product (g)} = \frac{(\text{areas of product } i) \times (\text{grams of liquid product})}{\text{total areas of liquid product}} \quad (3.1)$$

The conversion and selectivity of the product were measured by Equations 3.2 and 3.3, respectively:

$$\text{Conversion (\%)} = \frac{(\text{weight of feed input} - \text{weight of feed remaining}) \times 100}{\text{weight of feed input}} \quad (3.2)$$

$$\text{Selectivity of product } i(\%) = \frac{\text{moles of product } i \times 100}{\text{moles of overall products}} \quad (3.3)$$

3.5.2 Gas Products Analysis

GC/FID (Hewlett Packard 5890 series II) was used to analyze the composition of gas products. The GC operating condition was summarized as follows:
Injection temperature : 180 °C

Detector temperature : 250 °C

Carrier gas : He

Column type : capillary HP-PLOT/Al₂O₃ “S” deactivated column

The following chromatographic temperature program in Table 3.4 was used for gas product analysis:

Table 3.4 The chromatographic temperature program for gas-phase product analysis

Step	Temperature (°C)	Rate (°C/min)	Holding time (min)
1	40	-	3
2	70	15	0
3	170	5	0
4	190	1	0

For the quantitative calculation of gas product, the areas of each peak were analyzed hourly by GC/FID (Hewlett Packard 5890 series II) and were converted to gram unit by comparing with the area of methane from gas standard by mol% (equal to vol%), as shown in Equation 3.4.

Weight of product i(g) =

$$\frac{(\text{areas of product } i \text{ per } 1 \text{ ml}) \times (\text{mol of methane per } 1 \text{ ml}) \times \left(\text{overall gas product} \left(\frac{\text{ml}}{\text{h}}\right)\right)}{(\text{mol of carbon atom}) \times (\text{reference area of methane per } 1 \text{ ml}) \times \left(\text{molecular weight} \left(\frac{\text{g}}{\text{mol}}\right)\right)} \quad (3.4)$$

The calculations of conversion, selectivity, and yield of the product were defined as shown in Equations 3.5, 3.6 and 3.7, respectively.

$$\text{Conversion (\%)} = \frac{(\text{weight of feed input} - \text{weight of feed remaining}) \times 100}{\text{weight of feed input}} \quad (3.5)$$

$$\text{Selectivity of product } i(\%) = \frac{\text{moles of product } i \times 100}{\text{moles of overall products}} \quad (3.6)$$

$$\text{Yield of product } i(\%) = (\text{conversion}) \times (\text{selectivity of product } i) \quad (3.7)$$

2503957090

CHAPTER 4

RESULTS AND DISCUSSION

In this research, the monometallic (Co and Pd) and bimetallic (CoPd and NiPd) supported on HZSM-12 zeolite with various metal loadings and bimetallic CoPd with various zeolite supports (HZSM-12, HZSM-5, and HY) were synthesized by incipient wetness impregnation and characterized by X-ray diffraction (XRD), X-ray fluorescence (XRF), Brunauer-Emmett-Teller (BET), temperature programmed reduction (TPR), temperature programmed desorption (TPD) of ammonia, and transmission electron microscopy (TEM). The catalysts were tested for their catalytic activity in converting PFAD to bio-jet fuel. The spent catalysts were characterized by temperature programmed oxidation (TPO) and CHNS analyzer.

4.1 Characterization of Catalysts

4.1.1 X-ray Diffraction (XRD)

XRD patterns of the synthesized catalysts are shown in Figure 4.1. The synthesized ZSM-12 exhibited characteristic peaks at $2\theta = 7.36^\circ$, 8.80° , 20.88° , 22.88° , and 23.20° which correspond to plane (2,0,0), (2,2,-2), (3,1,0), (3,1,-3), and (0,0,6). The positions and relative intensities of the parent ZSM-12 agreed with the data from previous studies (Marcelo *et al.*, 2005). Moreover, the XRD peak intensity was slightly lower after the ZSM-12 was changed to acid form. The monoclinic cell parameters of HZSM-12 are shown in Table 4.1. The synthesized catalysts had similar lattice constants with a previous study (Fyfe *et al.*, 1990) so it can confirm that the synthesized catalysts are HZSM-12 zeolite supports. The characteristic peaks of palladium oxide (PdO) appeared at 29.26° (1,0,0) and 33.84° (1,0,1), cobalt oxide (CoO) peaks appeared at 31.22° (2,2,0) and 36.65° (3,1,1), and nickel oxide (NiO) peaks appeared at 37.07° (1,1,1) and 43.09° (2,0,0), corresponding to previous study (Ma *et al.*, 2019), (Guo *et al.*, 2010), and (Qiao *et al.*, 2009), respectively. For bimetallic 10Co1Pd/HZSM-12, 10Ni1Pd/HZSM-12, 10Co1Pd/HZSM-5, and 10Co1Pd/HY catalysts, the palladium oxide peaks were not clearly observed while

cobalt oxide and nickel oxide exhibited obvious peak because the higher metal loading resulted in an intense peak of the metal oxide (Ameen *et al.*, 2019). The results exhibited that XRD peaks were lower after loading metal because the framework structure was destroyed and had defects on zeolite during the thermal treatment according to the previous study (Kathrina *et al.*, 2013).

Figure 4.1 XRD patterns of synthesized catalysts.

Table 4.1 XRD data of the prepared HZSM-12

Catalysts	Theory				XRD			
	a (Å)	b (Å)	c (Å)	β (°)	a (Å)	b (Å)	c (Å)	β (°)
HZSM-12					25.20	5.08	24.66	107.7
10Co/HZSM-12	24.86	5.01	24.33	107.7	24.94	5.03	24.41	107.7
1Pd/HZSM-12					24.91	5.02	24.38	107.7

Table 4.1 (cont.) XRD data of the prepared HZSM-12

Catalysts	Theory				XRD			
	a (Å)	b (Å)	c (Å)	β (°)	a (Å)	b (Å)	c (Å)	β (°)
10Co1Pd/HZSM-12	24.86	5.01	24.33	107.7	25.07	5.05	24.53	107.7
10Ni1Pd/HZSM-12					25.20	5.08	24.66	107.7

4.1.2 X-ray Fluorescence (XRF)

X-ray fluorescence is a bulk analysis that was utilized to study the chemical composition of the synthesized HZSM-12. As shown in Table 4.2, the results showed that the Pd contents in the prepared 1Pd/HZSM-12, 5Co1Pd/HZSM-12, 10Co1Pd/HZSM-12, and 15Co1Pd/HZSM-12 catalysts were 0.51%, 0.60%, 0.65%, and 0.65%, respectively. Co contents in the prepared 10Co/HZSM-12, 5Co1Pd/HZSM-12, 10Co1Pd/HZSM-12, and 15Co1Pd/HZSM-12 catalysts were 8.43%, 4.32%, 8.19%, and 11.4%, respectively. The unexpected lower amount could be due to the loss during the preparation process.

Table 4.2 Chemical composition of the prepared catalysts

Catalysts	Co (wt. %)		Pd (wt. %)	
	Theory	XRF	Theory	XRF
10Co/HZSM-12	10	8.43	0	0
1Pd/HZSM-12	0	0	1	0.51
5Co1Pd /HZSM-12	5	4.32	1	0.60
10Co1Pd/HZSM-12	10	8.19	1	0.65
15Co1Pd /HZSM-12	15	11.4	1	0.65

4.1.3 Brunauer-Emmett-Teller (BET)

Brunauer-Emmett-Teller (BET) was used to explain the physical adsorption of gas molecules on a solid surface to find textural properties of the prepared catalyst. As shown in Table 4.3, the surface area of synthesized catalysts was measured by BET equation. External surface area and micropore volume were derived by V-t method, and total pore volume was obtained by Barrett-Jayner-Halenda (BJH). The results indicated that total surface area, external surface area, micropore volume, and total pore volume were decreased after metals loading which could block some micropore and mesopore of zeolite support (Silva *et al.*, 2004). 1Pd/HZSM-12 had the highest surface area and pore volume due to its low metal loading. 5Co1Pd/HZSM-12 had a higher surface area and pore volume than 10Co1Pd/HZSM-12 and 15Co1Pd/HZSM-12. The textural properties of 10Co/HZSM-12 and 10Co1Pd/HZSM-12 were not significantly different. In addition, different zeolite supports have different textural properties from their structures. The results exhibited that 10Co1Pd/HY had the highest surface area, followed by 10Co1Pd/HZSM-5, and 10Co1Pd/HZSM-12.

Table 4.3 Physical characteristics of the prepared catalysts

Catalysts	S_{BET} (m^2/g)	S_{ext} (m^2/g)	V_{micro} (cm^3/g)	V_{total} (cm^3/g)
HZSM-12	313	104	0.114	0.4036
1Pd/HZSM-12	297	104	0.105	0.3561
10Co/HZSM-12	243	82	0.088	0.3435
5Co1Pd/HZSM-12	254	82	0.094	0.3874
10Co1Pd/HZSM-12	244	84	0.088	0.3546
15Co1Pd/HZSM-12	224	79	0.079	0.3542
10Ni1Pd/HZSM-12	264	99	0.090	0.3946
10Co1Pd/HZSM-5	289	119	0.094	0.5469
10Co1Pd/HY	480	122	0.195	0.5158

4.1.4 Temperature Programmed Reduction (TPR)

The temperature programmed reduction was performed to determine the reduction temperature of catalysts. The TPR profiles of the different catalysts are shown in Figure 4.2. Initially, 10Co/HZSM-12 exhibited two peaks at approximately 300 – 360 °C and 360 – 530 °C, corresponded to the reducibility of Co_3O_4 to CoO and CoO to metal Co, respectively (Cao *et al.*, 2018). Furthermore, 1Pd/HZSM-12 had two TPR peaks at 50 – 60 °C from H_2 consumption to reduce both PdO and Pd(OH)₂ to form Pd hydride. Moreover, the negative peak demonstrated palladium hydride decomposition through H-diffusion into palladium crystallites because PdO species can reversibly transform to Pd(OH)₂ in the presence of water, this was similar to the previous study (Kim *et al.*, 2018). Bimetallic 10Co1Pd/HZSM-12 had two reduction temperature peaks. Firstly, the reduction temperature at 100 – 260 °C presented the reduction of Pd oxide species (either PdO or Pd(OH)₂) combined with cobalt oxide (Co_3O_4). Secondly, the reduction temperature at 260 – 360 °C referred to the reduction of cobalt oxide (CoO). The reduction temperature was shifted to lower temperature as compared to monometallic 10Co/HZSM-12. This indicated that cobalt and palladium have a strong interaction and the reducibility of metal oxide is facilitated after loading palladium in the catalyst (Dao *et al.*, 2015). Moreover, 10Ni1Pd/HZSM-12 showed reduction temperature at 250 – 360 °C.

Figure 4.2 H_2 -TPR profiles of 10Co1Pd/HZSM-12, 10Co/HZSM-12, 1Pd/HZSM-12, and 10Ni1Pd/HZSM-12.

4.1.5 Temperature Programmed Desorption (TPD) of Ammonia

The acidic properties of the calcined catalysts were characterized by temperature programmed desorption of ammonia. As shown in Figure 4.3, 1Pd/HZSM-12 exhibited peaks at 100 – 260 °C which referred to the desorption of NH₃ on weak acid site. 10Co/HZSM-12 exhibited two NH₃ desorption peaks 100 – 300 °C (weak acid site) and 350 – 540 °C (strong acid site). 10Co1Pd/HZSM-12 peak showed the same trend as 10Co/HZSM-12 but it had an intermediate peak at 260 – 360 °C because the transition metal has ability to introduce a new acid site. Both intermediate and strong acid peaks referred to difficult for desorption NH₃ on the acid sites (Gao *et al.*, 2019). 10Co1Pd/HY showed two NH₃ desorption peaks which consisted of a weak acid site at 100 – 250 °C and strong acid site at 250 – 400 °C. 10Co1Pd/HZSM-5 showed three peaks which are 100 – 320 °C (weak acid site), 350 – 490 °C (intermediate acid site), and 490 – 580 °C (strong acid site). Table 4.4 illustrates the SiO₂/Al₂O₃ molar ratio of zeolite supports from XRF and the acidity of synthesized catalysts from NH₃-TPD. HZSM-12 was synthesized with a molar composition of 100SiO₂: 1Al₂O₃: 1Na₂O: 25TEAOH: 1500H₂O. The XRF results showed SiO₂/Al₂O₃ molar ratios of all zeolite supports were higher than the theory, indicating lower acidity than expected. However, the SiO₂/Al₂O₃ molar ratios of all catalysts were not significantly different. Furthermore, the NH₃-TPD results showed that the acidity of catalysts increased after metal loading. 1Pd/HZSM-12 had the highest acidity, followed by 10Co1Pd/HZSM-12 and 10Co/HZSM-12, respectively. In addition, 1Pd/HZSM-12 had a high amount of weak acid sites while others had both weak and strong acid sites. As compared to different zeolite supports, 10Co1Pd/HZSM-5 catalyst had higher acidity than 10Co1Pd/HZSM-12, and 10Co1Pd/HY, respectively. The acidity is important for hydrocracking and isomerization reactions.

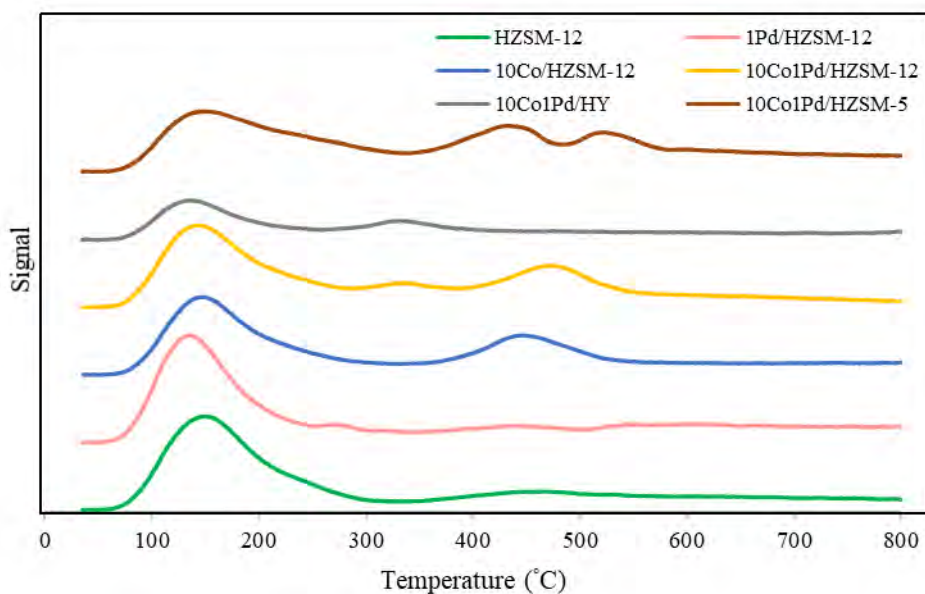

Figure 4.3 NH₃-TPD profiles of parent HZSM-12, 1Pd/HZSM-12, 10Co/HZSM-12, 10Co1Pd/HZSM-12, 10Co1Pd /HZSM-5, and 10Co1Pd /HY catalysts.

Table 4.4 Acidity of parent HZSM-12, 10Co1Pd/HZSM-12, 10Co/HZSM-12, 1Pd/HZSM-12, 10Ni1Pd/HZSM-12, 10Co1Pd/HZSM-5, and 10Co1Pd/HY from NH₃-TPD

Catalysts	SiO ₂ /Al ₂ O ₃		Acidity from NH ₃ -TPD (mmol/g)
	Theory	XRF	
HZSM-12	100	N/A	2.287
10Co/HZSM-12	100	114.49	2.359
1Pd/HZSM-12	100	122.29	3.227
10Co1Pd/HZSM-12	100	118.80	2.571
10Co1Pd/HZSM-5	100	N/A	2.987
10Co1Pd/HY	100	N/A	1.118

4.1.6 Transmission Electron Microscopy (TEM)

Transmission electron microscopy images of the prepared catalysts are illustrated in Figure 4.4. In Figure 4.4 (a), the parent HZSM-12 had a cubic shape with crystal size approximately equal to 600 nm (Silva *et al.*, 2019). Figures 4.4 (b) – (d) show metal dispersion of 5%, 10%, and 15% wt. Co loading with 1% wt. Pd loading on HZSM-12 supports. Cobalt showed a big spot due to its large particle size while palladium had a dark spot because of its high mass number. In Figures 4.4 (b) and 4.4 (c), 5Co1Pd/HZSM-12 and 10Co1Pd/HZSM-12 catalysts showed high metal dispersion which is auxiliary to occur deoxygenation reaction while 15Co1Pd/HZSM-12 catalyst had some cobalt aggregation in the support as shown in Figure 4.4 (d).

Figure 4.4 TEM images of (a) calcined HZSM-12 zeolite, (b) 5Co1Pd/ HZSM-12 zeolite, (c) 10Co1Pd/ HZSM-12 zeolite, and (d) 15Co1Pd/ HZSM-12 catalysts.

Figure 4.4 (cont.) TEM images of (a) calcined HZSM-12 zeolite, (b) 5Co1Pd/HZSM-12 zeolite, (c) 10Co1Pd/HZSM-12 zeolite, and (d) 15Co1Pd/HZSM-12 catalysts.

4.1.7 Temperature Programmed Oxidation (TPO)

Temperature Programmed Oxidation (TPO) profiles of spent catalysts are presented in Figure 4.5. 1Pd/HZSM-12 exhibited a peak at 320 – 420 °C which is due to the oxygen uptake for soft coke combustion. 10Co/HZSM-12 showed two peaks at 280 – 480 °C and 500 – 610 °C which corresponded to poorly and highly polymerized coke deposition on the catalyst, respectively. Meanwhile, 10Co1Pd/HZSM-12 exhibited peak from oxygen consumption at 200 – 360 °C. Because cobalt and palladium had strong interaction, the peak was shifted to the lower temperature as compared to monometallic Co or Pd on the same zeolite supports which referred to the ease of coke removal. 10Ni1Pd/HZSM-12 revealed the low intensity peak at 270 – 500 °C. 10Co1Pd/HZSM-5 exhibited two peaks from soft coke (280 – 450 °C) and hard coke (520 – 610 °C). 10Co1Pd/HY had a broad peak at 300 – 800 °C, indicating a high amount of hard coke according to the previous study (Rihko-Struckmann *et al.*, 2006).

Figure 4.5 Temperature Programmed Oxidation of 1Pd/HZSM-12, 10Co/HZSM-12, 10Co1Pd/HZSM-12, 10Ni1Pd/HZSM-12, 10Co1Pd/HZSM-5, and 10Co1Pd/HY catalysts.

4.1.8 CHNS Analyzer

Table 4.5 shows the quantities of carbon in catalysts. The amount of coke deposition was lower than carbon contents on spent catalysts since fresh catalysts also had some carbon deposition. Among HZSM-12 supported catalysts, the coke deposition in spent catalysts tended to decrease in the following order: 10Co1Pd/HZSM-12 > 10Co/HZSM-12 > 10Ni1Pd/HZSM-12 > 1Pd/HZSM-12. The strong acidity plays a significant role in coke formation. According to TPD-NH₃ profiles, both 10Co1Pd/HZSM-12 and 10Co/HZSM-12 catalysts had strong acid sites, leading to the ease of coke deposition (Gao *et al.*, 2016). Moreover, the interaction of Co and Pd presented the high activity that tends to form coke. Bimetallic

10Ni1Pd/HZSM-12 had a low coke since nickel mainly took part in the hydrogenation reaction. Therefore, it had a side reaction like methanation for converting carbon monoxide to methane. The low coke deposition is related to the removal of carbon in the form of CO_x during the reaction (Ameen *et al.*, 2019). The different zeolite supports were also studied, the amounts of the coke tended to decrease in the following order: 10Co1Pd/HY > 10Co1Pd/HZSM-5 > 10Co1Pd/HZSM-12. 10Co1Pd/HZSM-12 showed the lowest coke deposition since one-dimensional channel does not allow coke precursor penetrating inside (Zhang *et al.*, 1999) and 10Co1Pd/HZSM-5 also had shaped selective that limits coke into the pores (Weigert *et al.*, 1986). However, the HZSM-5 in this work had high acidity from Si/Al molar ratio of 50 which affects high coke formation according to the previous study (Gao *et al.*, 2016). 10Co1Pd/HY exhibited the highest amount of coke because it had large cavities of the pores that coke can be placed inside the pores (Schulz *et al.*, 2004).

Table 4.5 Amount of carbon deposits on spent catalysts from CHNS analyzer

Catalysts	Carbon of fresh catalysts (wt. %)	Carbon of spent catalysts (wt. %)
10Co/HZSM-12	1.642	20.50
1Pd/HZSM-12	1.655	16.53
10Co1Pd/HZSM-12	1.633	22.79
10Ni1Pd/HZSM-12	N/A	18.67
10Co1Pd/HZSM-5	N/A	24.66
10Co1Pd/HY	1.672	28.44

4.2 Gas Chromatography of Feed and Standard Analysis

4.2.1 Feed Analysis

The chromatogram and composition of PFAD, analyzed by GC/FID (Agilent 7890A) are shown in Figure 4.6, and Table 4.6, respectively. It was observed that PFAD contained palmitic acid and oleic acid as the main components (retention

times are 16.043 and 17.509, respectively), it also contained other components i.e. hexadecane, octadecane, steric acid, hexadecanol, monoglyceride, diglyceride, and triglyceride (retention times are 11.903, 13.898, 15.190, 17.737, 28.831, 32.960 – 34.377 and 35.937 – 37.254, respectively).

Table 4.6 Composition of PFAD feedstock

Feed components	Amount (% wt.)
Palmitic acid	46.48
Oleic acid	43.41
Stearic acid	4.00
Hexadecane	0.38
Octadecane	1.14
Monoglyceride	1.45
Diglyceride	2.28
Triglyceride	0.86

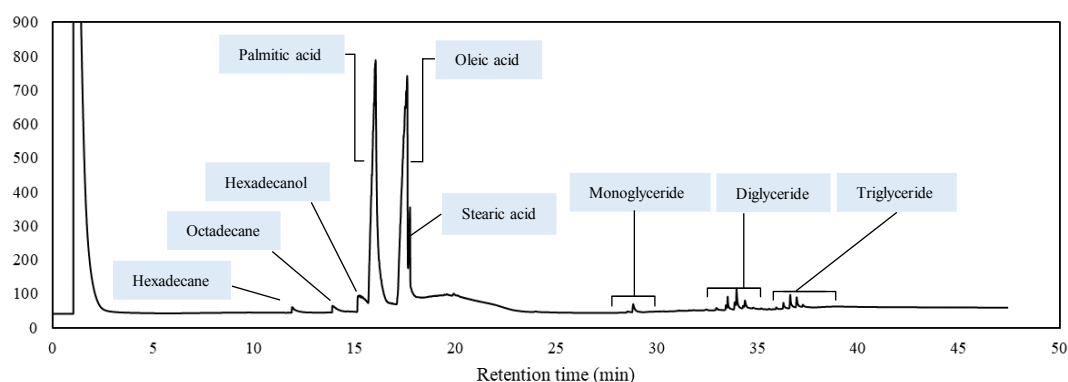

Figure 4.6 The chromatogram of various components in PFAD range analyzed by a GC/FID.

4.2.2 Standard Analysis

The chromatograms of liquid standards were analyzed by an Agilent 7890 gas chromatograph equipped with an FID detector to identify the peaks of non-polarity liquid standards (*n*-alkanes) and the polarity liquid standards (oxygenated

compounds). Figure 4.7 shows chromatograms of *n*-alkanes from ASTM 2887 standards, consisting of hexane (C6), heptane (C7), octane (C8), nonane (C9), decane (C10), undecane (C11), dodecane (C12), tetradecane (C14), hexadecane (C16), octadecane (C18), and eicosane (C20) (retention times are 1.056, 1.067, 1.127, 1.236, 1.481, 2.067, 3.446, 8.294, 11.125, 13.292, and 15.122, respectively). In addition, other *n*-alkanes; tridecanes (C13), and heptadecane (C17) had retention times at 6.35 and 12.233.

Figure 4.7 The chromatogram of various *n*-alkane components in ASTM 2887 standard analyzed by a GC/FID.

The chromatogram of oxygenated compounds standards is shown in Figure 4.8, consisting of hexadecanol, C20 internal standard, palmitic acid, octadecanol, oleic acid, and stearic acid (retention times are 14.828, 15.104, 15.662, 16.616, 17.079, and 17.376, respectively).

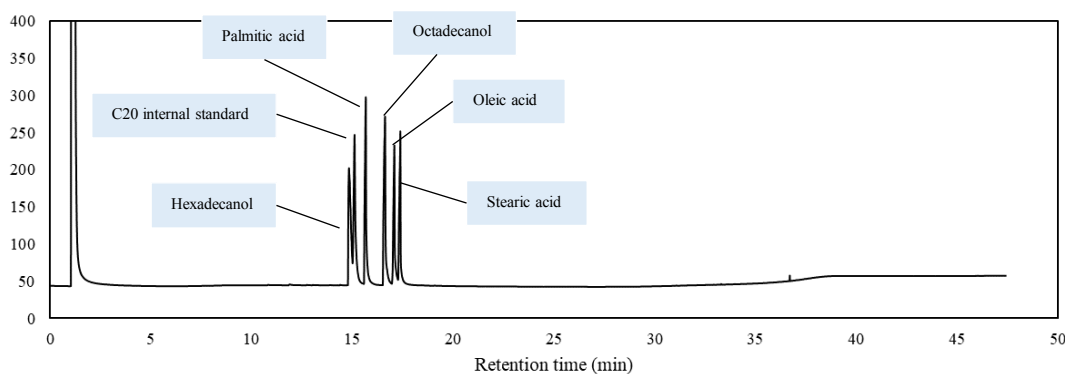

Figure 4.8 The chromatogram of oxygenated compounds standard analyzed by a GC/FID.

4.3 Catalyst Activity Testing

This section exhibits the performance of the prepared catalysts in terms of conversion of PFAD and product yield. Monometallic (Co and Pd) and bimetallic (CoPd and NiPd) supported on HZSM-12 zeolite with various metal loadings and bimetallic CoPd with various zeolite supports (HZSM-12, HZSM-5, and HY) were studied. The optimum reaction conditions (i.e. temperature, pressure, and LHSV) were also investigated.

4.3.1 Effect of Metal Loading

This section is divided into 3 parts including 1) Effect of mono- and bi-metallic CoPd supported on HZSM-12 2) Effect of Co loading on CoPd/HZSM-12 and 3) Comparison of CoPd/HZSM-12 and NiPd/HZSM-12.

4.3.1.1 Effect of Mono- and Bi-metallic CoPd Supported on HZSM-12

Figure 4.9 shows conversion and yield of products over 1Pd/HZSM-12, 10Co/HZSM-12, and 10Co1Pd/HZSM-12 catalyts at 350°C, 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8. All catalysts gave high conversion of PFAD (closed to 100%). After operating the system for 7 h, the conversion of 1Pd/HZSM-12 deactivated from 99.15% to 76.87% while other catalysts still gave high conversion almost 100%. Moreover, 1Pd/HZSM-12 exhibited the highest bio-jet fuel yield of 70.53% at TOS of 4 h then deactivated, giving bio-jet fuel 3.94% at TOS of 8 h. 10Co/HZSM-12 exhibited good stability at first 6 h with a yield higher than 30%. Finally, 10Co1Pd/HZSM-12 exhibited great stability without deactivation at

first 7 h with a conversion of 99.98% and yield of bio-jet fuel of 50.92%. According to CHNS results, the 1Pd/HZSM-12 catalyst activity dropped faster than 10Co/HZSM-12 and 10Co1Pd/HZSM-12 catalysts even though it had the lowest coke formation. Because the presence of cobalt in catalyst facilitates hydrogen adsorption on active sites (Dao *et al.*, 2015), hydrogen can further react with the nearby coke to stabilize the catalysts (Yang *et al.*, 2009). Moreover, 10Co/HZSM-12 and 10Co1Pd/HZSM-12 catalysts presented high PFAD conversion after 6 and 7 h, respectively. But, the yield of bio-jet decreased with the increasing of diesel. It can be expected that metal still had high activity in deoxygenation reaction but the acidity for hydrocracking was lower. The lower acidity could be from the sintering after the course of reaction at high temperature. The sintering process resulted in crystal agglomeration and further pore blocking, thus lowering catalyst active site for hydrocracking reaction (Nasrallah M, 2018).

2503957090

CU IThesis 6171003063 thesis / recv: 27072563 17:27:35 / seq: 25

Figure 4.9 The conversion of PFAD and product yield obtained over (a) 1Pd/HZSM-12, (b) 10Co/HZSM-12, and (c) 10Co1Pd/HZSM-12 (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8).

The conversion of PFAD and products yield over 1Pd/HZSM-12, 10Co1Pd/HZSM-12, and 10Co/HZSM-12 catalysts are presented in Figure 4.10. All catalysts gave high fraction of *i*-paraffins. Although 1Pd/HZSM-12 was highly active as shown in Figure 4.8, it produced 39.98 % bio-jet fuel which is lower than 10Co/HZSM-12 and 10Co1Pd/HZSM-12 (46.62% and 55.46%, respectively) at 6 h.

Moreover, the presence of bimetallic CoPd on HZSM-12 zeolite support not only enhanced the deoxygenation and hydrocracking for bio-jet fuel production, but also showed the highest stability as compared to the other catalysts.

Figure 4.10 The conversion and yield of products over 1Pd/HZSM-12, 10Co /HZSM-12, and 10Co1Pd/HZSM-12 catalysts (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.1.2 Effect of Co Loading on CoPd/HZSM-12 Catalysts

The conversion and yield of products over 5Co1Pd/HZSM-12, 10Co1Pd/HZSM-12, and 15Co1Pd/HZSM-12 catalysts at 350 °C, 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8 are presented in Figure 4.11. 5Co1Pd/HZSM-12 and 10Co1Pd/HZSM-12 gave high conversions of PFAD which were 93.90 % and 99.91 %, respectively while 15Co1Pd/HZSM-12 gave 84.73%. 5Co1Pd/HZSM-12 produced bio-jet fuel as well as biodiesel. On the other hand, 15Co1Pd/HZSM-12 produced higher biodiesel yield than bio-jet fuel. It is possible that metal agglomerates and blocks pore size of support as shown in TEM image so the catalyst had a lower ability for cracking. It can be summarized that 10Co1Pd/HZSM-12 had a suitable Co loading as compared to the others.

Figure 4.11 The conversion and yield of products over 5Co1Pd/HZSM-12, 10Co1Pd/HZSM-12, and 15Co1Pd/HZSM-12 catalysts (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.1.3 Comparison CoPd/HZSM-12 and NiPd/HZSM-12 Catalysts

The conversion and yield of products over 10Co1Pd/HZSM-12 and 10Ni1Pd/HZSM-12 catalysts at 350 °C, 30 bar, LHSV of 1.5 h⁻¹, and H₂/feed molar ratio of 8 are shown in Figure 4.12. Both 10Co1Pd/HZSM-12 and 10Ni1Pd/HZSM-12 exhibited almost complete conversion and produced high *i*-paraffins. Cobalt demonstrated C – C hydrogenolysis that produced 55.46% bio-jet fuel while nickel exhibited high deoxygenation route, but it showed the lower hydrocracking, so it produced biodiesel similar to bio-jet fuel which were 43.96% and 43.25%, respectively. The results were similar to the previous study (Zhang *et al.*, 2014). It can be concluded that cobalt is an appropriated non-noble metal for this reaction.

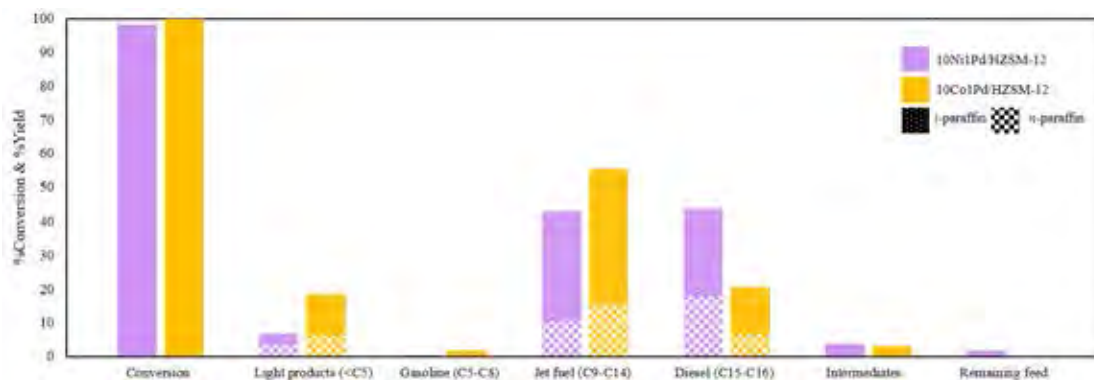

Figure 4.12 The conversion and yield of products over 10Ni1Pd/HZSM-12 and 10Co1Pd/HZSM-12 catalysts (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.2 Effect of Zeolite Supports

In this section, the effect of different zeolite supports including HZSM-12, HZSM-5, and HY on the catalytic activity of CoPd catalysts was investigated. Figure 4.13 shows the appearance of liquid products obtained over the catalysts with different supports as a function of time. The liquid products obtained from 10Co1Pd/HZSM-12 were clear at first 5 h while those from 10Co1Pd/HZSM-5 and 10Co1Pd/HY were yellow and brown. After TOS of 5 h, the product obtained over 10Co1Pd/HZSM-12 exhibited an orange color. 10Co1Pd/HZSM-5 products gave a lower amount of liquid product than other catalysts and changed color to orange in TOS = 7 h, and further became dark brown. The color of 10Co1Pd/HY products continuously changed from dark brown to light brown and white solid was observed after 6 h.

Figure 4.13 The appearance of liquid products obtained over different supports (a) 10Co1Pd/HZSM-12, (b) 10Co1Pd/HZSM-5, and (c) 10Co1Pd/HY (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8).

The conversion and yield of products over 10Co1Pd/HZSM-12, 10Co1Pd/HZSM-5, and 10Co1Pd/HY are shown in Figure 4.14. 10Co1Pd/HZSM-12 provided high bio-jet fuel which is higher than 50% at first 7 h. After that, intermediates were firstly observed. 10Co1Pd/HZSM-5 produced higher light gases than bio-jet fuel at first 5 h. After that, both light gases and bio-jet fuel became almost equal at 38%. For 10Co1Pd/HY, the high yield of gasoline occurred at first 2 h. After that, it decreased continuously while biodiesel product was increased sharply with time on stream, giving bio-jet fuel lower than 10 %.

Figure 4.14 The Conversion of PFAD and product yield obtained over (a) 10Co1Pd/HZSM-12, (b) 10Co1Pd/HZSM-5, and (c) 10Co1Pd/HY (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8).

Figure 4.15 demonstrates the conversion of PFAD and yield of products obtained over 10Co1Pd/HZSM-12, 10Co1Pd/HZSM-5, and 10Co1Pd/HY at 350°C, 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and time on stream of 6. All catalysts gave high conversion. The product distributions were directly affected by the structure of the zeolite catalysts. HZSM-12 has MTW structure that has high stability and resists to deposition of coke (Marcelo *et al.*, 2005). It produced 55.46% bio-jet

fuel with high *i*-paraffin since the pore mouth of HZSM-12 is suitable for transforming *n*-paraffin to *i*-paraffin (Ju *et al.*, 2016). HZSM-5 has MFI structure which is high stability because its channel does not allow the formation of the aromatic compound for leading coke (Weigert *et al.*, 1986). However, HZSM-5 has high acidity that affects excessive cracking with low isomerization thus it produced a high amount of light gases about 36.95% (Peng *et al.*, 2012). On the other hand, HY catalyst produced bio-jet fuel of 6.77% since FAU structure of HY has a big pore size that easily forms coke and causes low selective hydrocracking to produce a lighter product as bio-jet fuel. Moreover, it also had low isomerization (Castaño *et al.*, 2011). It can be expected that HZSM-12 is achieved catalyst support for jet fuel production purposes.

Figure 4.15 The conversion and yield of products over 10Co1Pd/HZSM-5, 10Co1Pd/HZSM-12, and 10Co1Pd/HY catalysts (Reaction condition: 350°C, 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.3 Effect of Reaction Temperature

In this section, the effect of reaction temperature was investigated. Figure 4.16 shows the conversion of PFAD and yield of products over 10Co1Pd/HZSM-12 catalyst at 30 bar, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8. The reaction temperature was varied from 325 – 375 °C. At 325 °C, PFAD was not completely converted and high amount of intermediates (42.02%) was observed. The yield of bio-jet fuel significantly increased at 350 °C with completely converting

PFAD because this temperature was high enough to crack the longer chain product like biodiesel and intermediates to bio-jet fuel. Moreover, at 375 °C almost complete conversion was observed. Although high amount of both intermediates and diesel were cracked, bio-jet fuel obtained only 37.37% and gasoline increased to 38.14%. It can be concluded that the reaction temperature significantly affected product selectivity. The optimal temperature for bio-jet fuel production is 350 °C (Wei *et al.*, 1996).

Figure 4.16 The conversion and yield of products over 10Co1Pd/HZSM-12 catalyst with different temperatures (Reaction condition: 30 bar, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.4 Effect of Reaction Pressure

In this section, the effect of reaction pressure was investigated. Figure 4.17 shows the conversion of PFAD and products yield over 10Co1Pd/HZSM-12 catalyst at 350 °C, LHSV= 1.5 h⁻¹, and H₂/feed molar ratio of 8 with various pressures (10 – 30 bar). The results showed that the conversion of PFAD and bio-jet fuel yield increased with pressure. The reaction at 30 bar exhibited the highest conversion at 99.91% with the highest bio-jet fuel yield at 55.46% while 10 and 20 bar demonstrated bio-jet fuel yield of 17.35%, and 38.93%, respectively. Moreover, high *i*-paraffin products were observed at 20 and 30 bar. High pressure had auxiliary to adsorb hydrogen on active site and dissolve hydrogen in PFAD on the catalyst which

is necessary for deoxygenation, hydrocracking, and isomerization reactions (Srifa *et al.*, 2014).

Figure 4.17 The conversion and yield of products over 10Co1Pd/HZSM-12 catalyst with different pressure (Reaction condition: 350°C, LHSV= 1.5 h⁻¹, H₂/feed molar ratio of 8, and TOS= 6 h).

4.3.5 Effect of Liquid Hourly Space Velocity (LHSV)

In this section, the effect of LHSV for bio-jet fuel production was investigated. Figure 4.18 shows the conversion and yield of products over 10Co1Pd/HZSM-12 catalysts at 350 °C, 30 bar, and H₂/feed molar ratio of 8. LHSV varied from 1.5 to 2.5 h⁻¹. Decreasing LHSV led to the lower intermediates and diesel and the higher bio-jet fuel yield with high isomer products since the catalyst had more contact time with PFAD so the intermediates can be cracked and produced lighter products like bio-jet fuel.

Figure 4.18 The conversion and yield of products over 10Co1Pd/HZSM-12 catalysts with different LHSV (Reaction condition: 350°C, 30 bar, H₂/feed molar ratio of 8, and TOS= 6 h).

4.4 The Proposed Reaction Pathway

The proposed reaction pathway of palmitic acid which is a major component of palm fatty acid distillate is illustrated in Figure 4.19. Palmitic acid can be further converted into saturated hydrocarbons in diesel range by deoxygenation reaction. During the deoxygenation process, oxygen is removed from fatty acid then forms to H₂O and/or CO_x. Deoxygenation reaction can be divided into three types, consisting of hydrodeoxygenation (HDO), decarboxylation (DCO₂), and decarbonylation (DCO) (Coumans *et al.*, 2017). First, hydrodeoxygenation reaction (HDO) is oxygen exclusion process which is necessary to consume high hydrogen pressure and temperature to direct scission of C – O bond. Palmitic acid is transformed to hexadecanal via hydrogenolysis. Hexadecanal is converted to 1-hexadecanol by hydrogenated. After that, hexadecane is further produced from 1-hexadecanol through dehydrogenated reaction. Second, decarbonylation reaction (DCO) is the removal of carbonyl group, the primary reaction to form hexadecanal is firstly occurred hydrogen consumption. Subsequently, hexadecanal has transformed to pentadecane and CO by C – C bond scission. Moreover, 1-hexadecanol can also transform to pentadecane through decarbonylation reaction by removing CO and water. Third, decarboxylation reaction (DCO₂) is the removal of carboxyl group with no hydrogen consumption and

directly form pentadecane. Furthermore, hydrocracking reaction converts straight long chain-like diesel range to bio-jet fuel product by adding hydrogen. Moreover, the isomerization process converted straight-chain (*n*-paraffin) to branched-chain (*i*-paraffin) by removing hydrogen to form olefin and further produce various isomer products (Srifa *et al.*, 2015).

Figure 4.19 The proposed reaction pathway of bio-jet fuel production from palmitic acid over bi-functional catalysts.

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions

In this study, monometallic (Co and Pd) and bimetallic (CoPd and NiPd) supported on HZSM-12 zeolite with various metal loadings and bimetallic CoPd with various zeolite supports (HZSM-12, HZSM-5, and HY) were investigated to find the suitable catalyst for converting PFAD to bio-jet fuel product. The synthesized catalysts were confirmed by XRD, XRF, and TEM images. The acidity of catalysts enhanced after metals were loaded to zeolite support as shown in the TPD results. 10Co1Pd/HZSM-12 exhibited high catalyst activity and stability as compared to monometallic (Co or Pd) and bimetallic (NiPd) with the same zeolite supports. This could be due to its suitable acidity for cracking and isomerization to the product in jet fuel range. Moreover, 10Co1Pd/HZSM-12 exhibited low coke formation as compared to other zeolite supports since its pore size does not allow penetration of coke precursor, according to TPO and CHNS analyzer. 10Co1Pd/HZSM-5 demonstrated high acidity, resulting in a low bio-jet fuel. 10Co1Pd/HY had a large pore size and low acidity thus presenting low hydrocarbons in jet fuel range. The optimum reaction conditions for 10Co1Pd/HZSM-12 was found at 350 °C, 30 bar, LHSV of 1.5 h⁻¹, and H₂/Feed molar ratio of 8, giving 55.46% bio-jet fuel yield.

5.2 Recommendations

The 10Co1Pd/HZSM-12 catalyst exhibited high conversion until TOS = 7. However, the intermediates began to increase after TOS = 6 h. It is possible that catalyst began to deactivation, as a result, this catalyst should be further studied.

Carbon monoxide and carbon dioxide should be considered to investigate the production pathway.

APPENDICES
