Wanwipa Leangsiri : DEOXYGENATION OF PALM FATTY ACID  
DISTILLATE TO GREEN DIESEL OVER MOLYBDENUM NITRIDE  
AND CARBIDE-BASED CATALYSTS IN A TRICKLE-BED  
REACTOR. Advisor: Prof. SUTTICHAJ ASSABUMRUNGRAT Co-  
advisor: Asst. Prof. Worapon Kiatkittipong

In this present work, the deoxygenation of palm fatty acid distillate (PFAD) to green diesel over  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> supported bimetallic CoMo and NiMo carbide and nitride catalysts was conducted in a trickle bed reactor. The catalysts were prepared by a single-step decomposition method of mixture containing hexamethylenetetramine and corresponding metal salts in presence of hydrogen and nitrogen for carbide and nitride forms, respectively at 700 °C. The prepared catalysts were characterized by XRD, XPS, N<sub>2</sub>-sorption, SEM/EDX and TGA techniques. The catalyst performance was evaluated at a temperature of 330 °C, hydrogen pressure of 5 MPa, LHSV of 1 h<sup>-1</sup>, and H<sub>2</sub>/feed ratio of 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>). It was found that the carbide catalysts exhibited the superior performance that those of nitride catalysts. The bimetallic CoMoC showed higher diesel yield than monometallic Mo carbide and bimetallic NiMoC catalysts. Thus, the CoMoC and NiMoC catalysts were selected for further investigations. The catalysts prepared by a single-step decomposition method exhibited higher catalytic activity than that of catalysts prepared by temperature-programmed reduction method due to higher catalyst surface area. In order to optimize the operating conditions, the operating temperatures were varied from 300 to 390 °C under 3-5 MPa of hydrogen pressure. The operating temperature of 330 °C and 5 MPa of hydrogen pressure was found to be a suitable condition for CoMoC and NiMoC catalysts. In the stability test, the CoMoC catalyst exhibited complete PFAD conversion with diesel yield 82.0% for 72 h. time on stream. However, the catalytic activity of CoMoC catalyst gradually decreased after 72 h. and PFAD conversion of 81% with diesel yield of 68.5% were obtained after 102 h. time on stream.

## ACKNOWLEDGEMENTS

I would like to sincerely grateful for everyone contributing to the completion of my thesis. However, my appreciation extends to those whose names are not mentioned here.

First of all, I really appreciate and would like to express my sincere thankfulness to my thesis advisor, Prof. Suttichai Assabumrungrat and my co-advisor, Assist. Prof. Worapon Kiatkitipong for supervision, guidance, suggestions and continuous support throughout my research.

I would like to grateful to Dr. Akawat sririsuk as the chairman, Assist. Prof. Palang bumroongsakulsawat as a member of the thesis committee and Dr. Atthapon Srika as a member of the external examiner, for their helpful comments and suggestions.

Moreover, I would like to grateful to the scientists, my seniors, my friend, who are the members of the Center of excellence on catalysis and catalytic reaction engineering, Chulalongkorn University and Catalytic reaction, Silpakorn University, for the assistance and support of my research.

Finally, I would give my deepest thanks to my family, who always supports, encourages, and understands.

Wanwipa Leangsiri

## CHAPTER I

### INTRODUCTION

#### 1.1 Introduction

The global warming problem is a trend to increase as the population increases. Increased CO<sub>2</sub> emissions are the main cause of global warming caused by human activities and many sectors. Transportation is a one of the sectors with the highest amount of CO<sub>2</sub> emission. These problems have many effects on our world both directly and indirectly [1]. As a result, many sectors have looked for the process to reduce CO<sub>2</sub> emission by improvement the clean fuel, so-called biofuel to replace fossil fuel by carbon-neutral cycle concept at the same time, the biofuel can be produced from biomass.

The biofuel was generated from biomass and their properties are similar to fossil fuel. Many plants have oil as the main component and can be used to produce fuel. There are many types of energy plants in Thailand such as palm oil, jatropha oil, soybean oil and rapeseed oil. In addition, waste cooking oil is a potential raw material to produce renewable fuels.

In the first-generation, many researchers are focusing on biofuel obtained from edible vegetable oil, animal fat or waste cooking oil by transesterification so called biodiesel (FAME) [2-4]. The food encroachment of humanity has resulted in efforts to find new biomass as a reactant of biofuel products. Biodiesel is a fuel that has oxygen content in molecules, which must be mixed with petroleum fuel to be used with diesel engines. The next generation of biofuel, bio-hydrogenated diesel or green diesel production via hydrotreating of waste cooking oil, nonedible vegetable oil and free fatty acid (FFA) [5-9]. Which has a structure like petroleum fuel, can be used instead of fuel without blend other fuels. In hydrotreating process, the free fatty acids can be used as a reactant instead of triglyceride for synthetic diesel production.

Palm fatty acid distillate (PFAD) is a by-product of refining crude palm oil which contains approximately 93.2% of free fatty acid including palmitic acid, oleic acid and linoleic acid [10]. Palm fatty acid distillate is a potential feedstock for producing green diesel *via* hydrodeoxygenation.

Sulfide NiMo/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalysts and Pd/C are the commercial catalysts to produce green diesel, which are highly effective and have been studied in many research [11-14]. On the other hand, the sulfur content of sulfide NiMo/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst in the product resulted in increase in purification costs in addition to cause an

air pollution by emission of  $\text{SO}_x$ . Therefore, this research aims to develop non-sulfide catalysts from transition metals in carbide and nitride forms.

## 1.2 Objectives of research

To develop nickel and cobalt promoted molybdenum nitride and carbide catalysts for deoxygenation of palm fatty acid distillate to green diesel in a trickle bed reactor.

## 1.3 Scope of Research

1.3.1. The transition carbide and nitride catalyst ( $\text{MoC}/\text{Al}$ ,  $\text{MoN}/\text{Al}$ ,  $\text{CoMoC}/\text{Al}$ ,  $\text{CoMoN}/\text{Al}$ ,  $\text{NiMoC}/\text{Al}$  and  $\text{NiMoN}/\text{Al}$ ) were prepared by a single-step decomposition method in compared with conventional temperature-programmed reduction (TPR) method.

1.3.2. The synthesized catalysts were characterized XRD, XPS,  $\text{N}_2$  sorption, SEM/EDX and TGA analysis. and liquid products were analyzed by CHNO/S analyzer, FT-IR and gas chromatography equipped with a flame ionization detector (FID). The compositions of gas products were analyzed by gas chromatography equipped with a thermal conductivity detector (TCD).

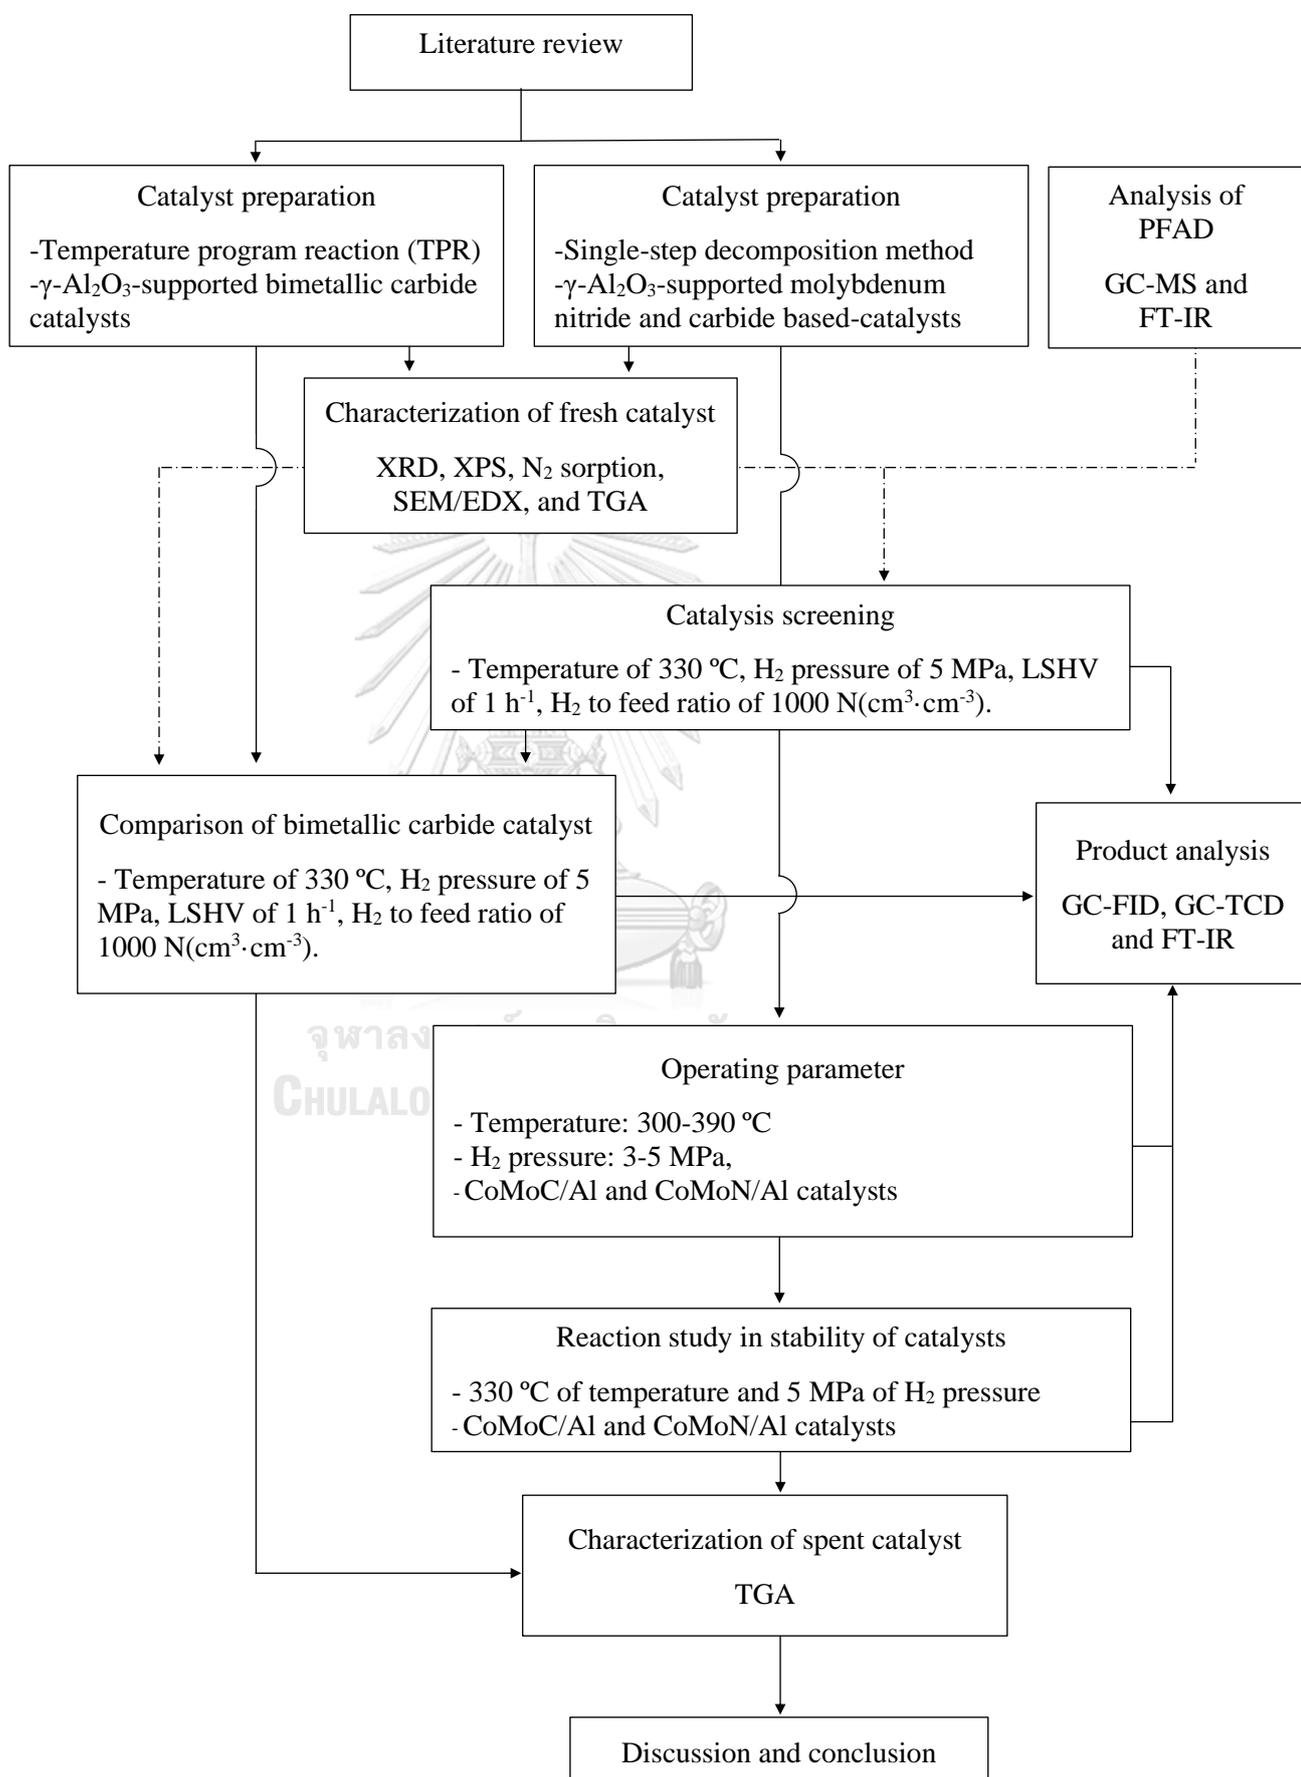

1.3.3. The catalyst performance was evaluated in a trickle-bed reactor under  $330\text{ }^\circ\text{C}$  of temperature, 5 MPa of hydrogen pressure,  $1\text{ h}^{-1}$  of LHSV and  $1000\text{ N}(\text{cm}^3 \cdot \text{cm}^{-3})$  of  $\text{H}_2/\text{feed}$  ratio.

1.3.4. The catalytic activities of bimetallic carbide catalysts ( $\text{CoMoC}/\text{Al}$  and  $\text{NiMoC}/\text{Al}$ ) prepared by a single-step decomposition method were compared with the catalysts prepared by conventional temperature-programmed reduction (TPR) method.

1.3.5. The reaction parameters for green diesel using the excellent catalysts under temperature ( $300\text{-}390\text{ }^\circ\text{C}$ ) and hydrogen pressure (3-5 MPa) were optimized.

1.3.6. The stability of the excellent catalysts was evaluated *via* hydrotreating of palm fatty acid distillate (PFAD) under optimal conditions.

## 1.4 Research methodology

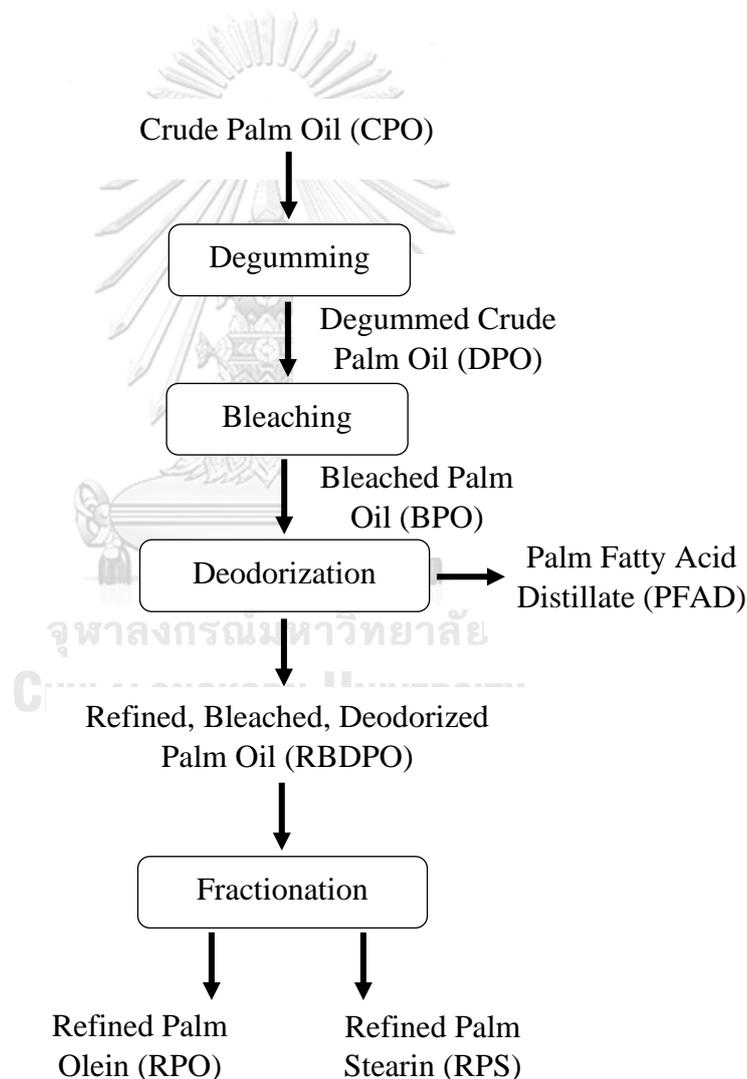

## CHAPTER II

### THEORY

#### 2.1 Palm fatty acid distillate (PFAD)

Palm fatty acid distillate (PFAD) is a by-product of the physical refining process of crude palm oil. The physical refining process of crude palm oil is shown in Figure 1. palm fatty acid distillate (PFAD) in crude palm oil (COP) consists of about 4-5% by the refining palm oil process, which is separated from the deodorization process.

**Figure 1** Physical refining process of crude palm oil [15].

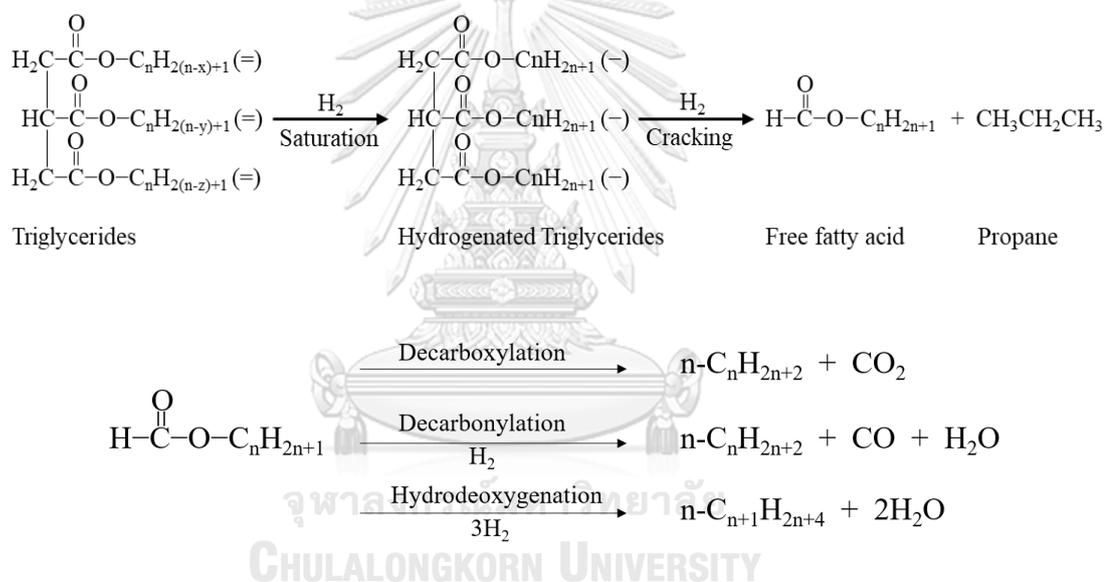

Palm fatty acid distillate (PFAD) is a potential feedstock to produce a new generation of biofuel. Palm fatty acid distillate (PFAD) consists of 93.2 wt % FFA that mainly contains 49.0% palmitic acid, 35.8% oleic acid, and 8.3% linoleic acid with a small amount of other fatty acids and triglycerides, as shown in Table 1. Palm fatty acid distillate (PFAD) is a light brown solid at room temperature, which melts into a brown liquid at temperatures between 60 to 70 °C [16].

**Table 1** Composition of FFA in PFAD [10].

<b>Fatty acid</b>	<b>Wt. %</b>
C14:0 (myristic acid)	1.1
C16:0 (palmitic acid)	49.0
C16:1 (palmitoleic acid)	0.2
C18:0 (stearic acid)	4.1
C18:1 (oleic acid)	35.8
C18:2 (linoleic acid)	8.3
C18:3 (linolenic acid)	0.3
C20:0 (arachidic acid)	0.3
C20:1 (eicosenoic acid)	0.2
C24:1 (tetracosenoic acid)	0.6

## 2.2 Hydrotreating process

The hydrotreating process can be converted triglyceride to n-alkane and iso-alkane at high temperature and high hydrogen pressure. First, the double bonds in the saturated molecule of triglycerides were hydrogenated to the unsaturated molecule of triglycerides, after that cracked to free fatty acid and propane. The free fatty acid eliminates oxygen content in molecules through three main reaction pathways for deoxygenation of free fatty acid to green diesel fuel generally consists of hydrodeoxygenation (HDO), decarbonylation (DCO) and decarboxylation (DCO<sub>2</sub>), as shown in Figure 2. The other possible reaction occurs in the hydrotreating process revers water gas shift and methanation reaction are shown in Figure 3. The thermodynamic data of deoxygenation reaction and other possible reaction was shown in Table 2.

**Figure 2** Reaction pathways for deoxygenation reaction of triglycerides to green diesel [17].

Water gas shift

Methanation

**Figure 3** The other possible reaction occurs in the deoxygenation reaction [18, 19].

**Table 2** The thermodynamic data of deoxygenation reaction and other possible reaction [19].

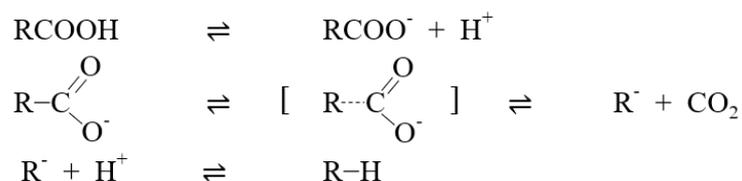

Liquid phase	Reaction	$\Delta G^{\circ}_{533}$ (kJ mol <sup>-1</sup> )	$\Delta H^{\circ}_{533}$ (kJ mol <sup>-1</sup> )
Hydrodeoxygenation	R-COOH + 3H <sub>2</sub> → R-CH <sub>3</sub> + 2H <sub>2</sub> O	-88.0	-112.6
Decarbonylation	R-COOH + H <sub>2</sub> → R-H + CO + H <sub>2</sub> O	-59.5	49.7
Decarboxylation	R-COOH → R-H + CO <sub>2</sub>	-78.6	10.1
Gas phase	Reaction	$\Delta G^{\circ}_{533}$ (kJ mol <sup>-1</sup> )	$\Delta H^{\circ}_{533}$ (kJ mol <sup>-1</sup> )
Methanation	CO + 3H <sub>2</sub> → CH <sub>4</sub> + H <sub>2</sub> O	-88.4	-215.3
Methanation	CO <sub>2</sub> + 4H <sub>2</sub> → CH <sub>4</sub> + 2H <sub>2</sub> O	-69.2	-175.7
Water gas shift	CO + H <sub>2</sub> O → CO <sub>2</sub> + H <sub>2</sub>	-19.1	-39.6

### 2.2.1 Hydrodeoxygenation (HDO)

Hydrodeoxygenation (HDO), an exothermic reaction, converts free fatty acid to n-alkane, which the same carbon number of free fatty acid and removes oxygen of free fatty acid in the form of water as a by-product.

### 2.2.2 Decarboxylation (DCO<sub>2</sub>)

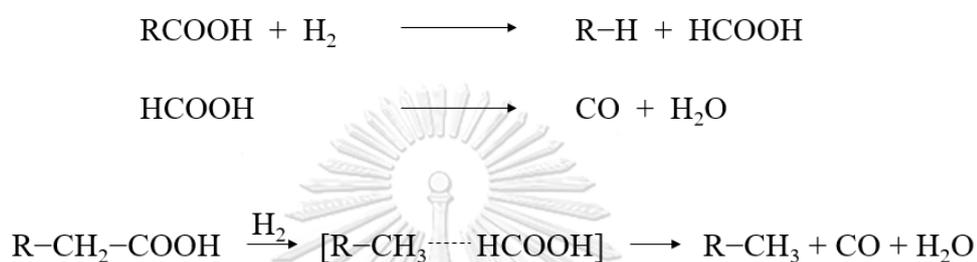

Decarboxylation (DCO<sub>2</sub>), an endothermic reaction, convert the carboxyl groups in free fatty acid to n-alkane. Reaction pathway of free fatty acid to n-alkane are shown in Figure 4. First, the H-O bond cleaved to hydrogen ions and the carboxylate anions. Next, the carboxylate anion break to alkyl anions and carbon dioxide, which the carbon atom of free fatty acid loses to CO<sub>2</sub> (as a by-product). Finally, the alkyl anions react with H<sup>+</sup> to generate n-alkane. Therefore, the carbon number of a product by decarboxylation reaction reduces one number.

**Figure 4** The reaction mechanism of free fatty acid to n-alkane [18].

### 2.2.3 Decarbonylation (DCO)

Decarbonylation (DCO), an endothermic reaction, comprise of two possible reaction pathways: (1) fatty acids are broken in the C–C bond, and then combine with H to give unsaturated straight-chain alkanes and lose acyl in form of CO. (2) saturated straight-chain alkanes and formic acid occur by direct hydrogenated of free fatty acid, then formic acid rapid decomposition to CO and H<sub>2</sub>O as a byproduct. Therefore, the carbon number of a product by both decarbonylation reaction reduces to one number. The direct hydrogenate of free fatty acid to saturated straight-chain alkanes and decomposition of formic acid shown in Figure 5.

**Figure 5** The reaction mechanism of free fatty acid to n-alkane by Decarbonylation [18, 20].

#### 2.2.4 Isomerization and cracking

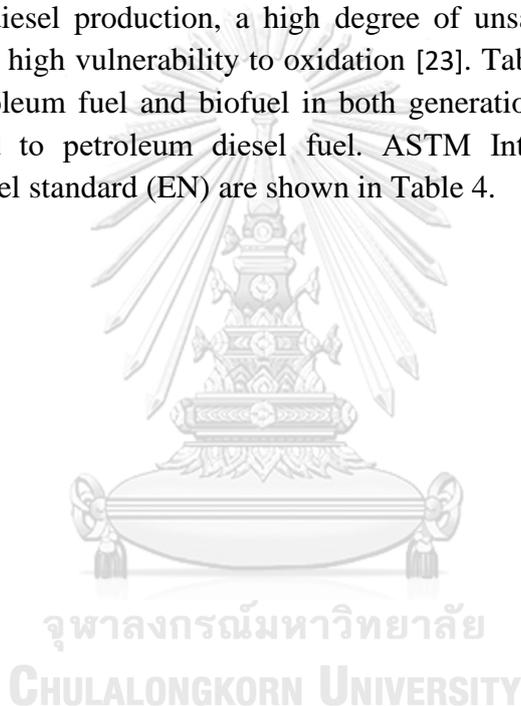

The n-alkane can be isomerization and cracking to produce iso-alkane and light hydrocarbon at the high reaction temperature, respectively. The n-alkane have a high cetane number, which good green diesel fuel properties. Therefore, isomerization and cracking reactions of n-alkane should be minimized [21]. On the other hand, the high amount of n-alkanes in green diesel fuel may also increase the cloud point and viscosity, and isomerization of the n-alkane may be desired [22].

#### 2.2.5 Revers water-gas shift and Methanation reaction

Carbon dioxide, carbon monoxide and hydrogen are gas products by deoxygenation of free fatty acid to green diesel. Methane and water occur by methanation of carbon monoxide and hydrogen. Carbon monoxide reacts with water to produce carbon dioxide and hydrogen via a reverse water-gas shift.

## 2.2 Green diesel

Green diesel is renewable energy from biomass through a chemical process, which are also known as an organic liquid product. Green diesel are suitable for replacing petroleum diesel because it reduces CO<sub>2</sub> emissions and has properties similar to petroleum diesel. While petroleum diesel has sulfur and impurity content, are produce NOK (SO<sub>x</sub> and NO<sub>x</sub>), which are air pollution, when combustion in diesel engines. In addition, hydrodesulfurization (HDS) as a sulfur removal unit are expensive cost. Including, when biodiesel as a first-generation biofuel compares with green diesel. Biodiesel has oxygen content in the molecule so it must blend with petroleum diesel before used for diesel engines. Because biodiesel quality depends on feedstock for biodiesel production, a high degree of unsaturation makes a melting point lower causes high vulnerability to oxidation [23]. Table 3 shown comparing the properties of petroleum fuel and biofuel in both generations. The property of green diesel fuel closed to petroleum diesel fuel. ASTM International's standard and European diesel fuel standard (EN) are shown in Table 4.

**Table 3** The physicochemical properties of diesel specification, biodiesel and green diesel [24, 25].

Parameter	EURO-IV Diesel specifications	FAME (Biodiesel)	BHD (Green diesel)
Density (kg m <sup>-3</sup> )	820-840	881	780
Viscosity at 40 (°C)	2.0-4.5	4.41	2.5-3.5
Flash point, min (°C)	35-66	168	120-138
Pour point, max (°C)	3.0-15.0	5	9
Cloud point (°C)	-5	1	-15 to -30
Calorific value (MJ kg <sup>-1</sup> )	-	37.98	44
Cetane number, min	51	50.8	80-90
Acid number (mg KOH g <sup>-1</sup> )	-	0.43	33.3
Sulphur content, max (mg kg <sup>-1</sup> )	50	20	< detection limit
Oxygen content (Wt.%)	-	12.8	-
Distillation (°C)	-	394	265-320
Lubricity (HFRR), max. (µm)	460		360
Heating value (MJ kg)	43	38	44

**Table 4** The standard test physical and chemical property of an organic liquid product [26, 27].

Properties	Unit	Method	
		European diesel fuel standard (EN)	ASTM

Aromatics	vol.%		ASTM D-1319
Total acid number (TAN)	mgKOH g <sup>-1</sup>		ASTM D-664

## CHAPTER III

### LITERATURE REVIEWS

#### 3.1 Feed for green diesel

Vegetable oil are an interesting source for green diesel production due to the mainly carbon atom in a range of the C<sub>12</sub>-C<sub>18</sub>, which is suitable for green diesel [28]. Vegetable oils contain triglycerides and free fatty acids, which triglyceride requires hydrogen consumption more than free fatty acids. Triglyceride needs to hydrogenate to free fatty acid and propane before deoxygenation reaction [17]. The free fatty acids are a potential raw material that is sustainable to produce green diesel because of low hydrogen consumption. hydrogen is an important raw material for green diesel production and expensive. In recent years, many studies have used free fatty acids, residues from the vegetable oil industry or model compounds, as raw materials instead of edible oil [29-37].

#### 3.2 Sulfide catalysts

Sulfide catalysts are commercial catalysts in deoxygenation for green diesel. In industrial, sulfide catalysts are of importance to remove the sulfur and nitrogen from petroleum. The sulfide form of catalyst had a remarkable effect on deoxygenation reactions. Normally, molybdenum or tungsten is used as a major ingredient and nickel or cobalt.

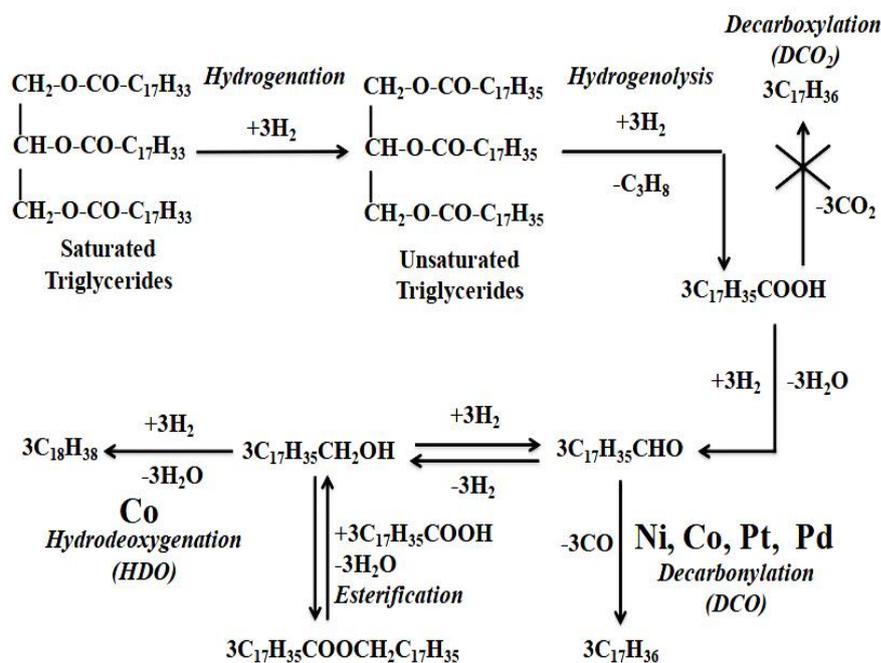

Srifah et al. [38] studied the deoxygenation of palm oil for bio-hydrogenated diesel by NiMoS<sub>2</sub>/γ-Al<sub>2</sub>O<sub>3</sub> catalyst in a continuous fixed-bed reactor. This research varied conditions of 270-420 °C, 15-80 bar, 0.25-5.0 h<sup>-1</sup> and hydrogen to oil ratio of 250-2000 N(cm<sup>3</sup> cm<sup>-3</sup>). The results showed the product yield of 90.0% with 300 °C of temperature, 30-50 bar of hydrogen pressure, 1.0-2.0 h<sup>-1</sup> of LSHV and 750-1000 of hydrogen to oil ratio. The increased temperature from 300 °C to 420 °C with a decrease in product yield from 89.8% to 37.9% because of the promotion of isomerization, cracking, and cyclization. Higher pressure promoted HDO reaction while the increases in LHSV suppressed reactions due to insufficient contact time. Furthermore, methanation reaction impacted on hydrogen consumption at low temperature and high pressure. Furthermore, low temperature and high pressure impacted on hydrogen consumption with methanation reaction.

Yang et al. [39] studied biofuel production via Hydrotreating of C<sub>18</sub> fatty acids over commercial sulfide Ni-W supported on modified SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> by NTY zeolite catalyst, which dodecane as a solvent in a fixed bed reactor. Interested, the effects of operating conditions are temperature 300-375 °C, pressure 2-8 MPa, WHSV 4-18 h<sup>-1</sup> and hydrogen to oil ratio 500-1000 N(mL mL<sup>-1</sup>). The results showed temperature increasing with decreases the amount of diesel fraction while the total isomerization ratio increases because higher temperature promotes cracking reactions and restrains hydrogenation reactions. Low WHSV would promote cracking reactions causes to reduce the C<sub>15</sub>-C<sub>18</sub> yield and the isomerization ratio of the diesel fraction. High pressure and low C<sub>18</sub> fatty acids concentration would promote the HDO while restraining the DCO/DCO<sub>2</sub> reactions due to the high ratio of adsorbed hydrogen to adsorbed C<sub>18</sub> fatty acids molecules.

Toba et al. [40] studied the hydrodeoxygenation (HDO) of waste cooking oil over sulfide NiMo/Al<sub>2</sub>O<sub>3</sub>, CoMo/Al<sub>2</sub>O<sub>3</sub> and NiW/Al<sub>2</sub>O<sub>3</sub> catalysts were to produce high-quality transportation fuel. The result shows all sulfide catalysts showed high HDO activity and all waste oils gave n-paraffins, iso-paraffins and a small amount of olefins. NiMo and NiW catalysts showed high and stable hydrogenation activity, whereas the deactivation of hydrogenation activity was observed using CoMo catalyst. NiW catalyst promoted decarboxylation or decarbonylation than NiMo and CoMo catalysts. NiMo and NiW catalysts are more suitable for hydrodeoxygenation of low-grade waste oils than CoMo catalyst to prevent the formation of olefin. Sulfur eliminated from the sulfide catalyst and dissolved into a product at the initial stage of the reaction, while sulfur content of the product was low when catalytic activity showed constantly.

### 3.3 Noble metal and metal catalysts

Srifah et al. [41] studied the green diesel production via the hydrodeoxygenation of palm olein using monometallic catalysts (Co, Ni, Pd, and Pt) on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> in a continuous trickle-bed reactor under the conditions are 270-420 °C of temperature, 15-80 bar of hydrogen pressure, 0.25-5.0 h<sup>-1</sup> of LSHV, and 250-2000 N(cm<sup>3</sup> cm<sup>-3</sup>) of hydrogen to oil ratio. The catalysts with various metal loadings (2–10 wt.%). The result showed the catalyst activity decreased in the order of product yield Co > Pd > Pt > Ni, compared at the same amount of metal loading. The Ni, Pd and Pt catalyst on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> promoted decarbonylation reaction more than hydrodeoxygenation reaction. Simultaneously, the Co/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst was nearly comparable between decarbonylation and/or decarboxylation with hydrodeoxygenation reaction. The reaction network of the model compound and oleic acid over the Ni, Co, Pd and Pt catalyst on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> shown in Figure 6.

**Figure 6** The reaction network of Ni, Co, Pd and Pt catalyst on  $\gamma\text{-Al}_2\text{O}_3$  [41].

Snåre et al. [42] studied the screening of metal catalysts (Pd, Pt, Ru, Mo, Ni, Rh, Ir, and Os) supported on carbon,  $\text{Al}_2\text{O}_3$ , and  $\text{SiO}_2$  for production of diesel-like hydrocarbons via catalytic deoxygenation of stearic acid in a semi-batch reactor. The condition was constant at 300 °C of temperature and 6 bars of hydrogen pressure. The catalysts screening results show highly active and selective in the deoxygenation of the reaction of palladium catalysts on carbon-supported, which converted stearic acid completely with > 98% selectivity toward deoxygenated  $\text{C}_{17}$  products. The outcome of comparison with different metals on the equivalent supports by same metal content that the beneficial effect of metal in the deoxygenation reaction is in the descending order  $\text{Pd} > \text{Pt} > \text{Ni} > \text{Rh} > \text{Ir} > \text{Ru} > \text{Os}$  catalysts. Furthermore, the decarboxylation reaction was more radical over the Pd/C catalyst, while the decarbonylation reaction was more apparent over the Pt/C catalyst.

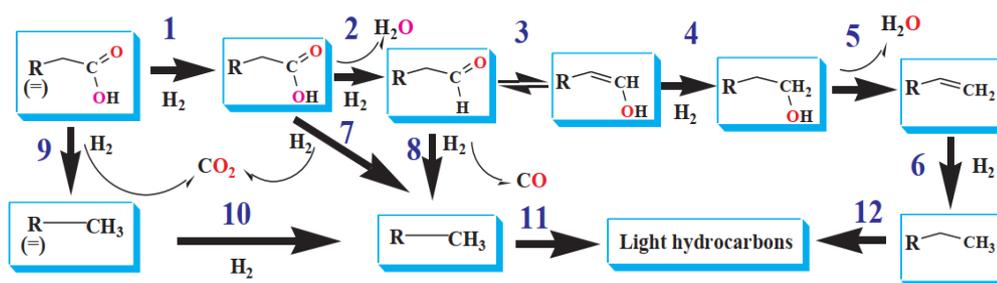

### 3.4 Metal carbides, metal nitrides and metal phosphides catalysts

Phimsen et al. [13] studied the effect of nickel catalysts i.e. nickel sulfide (NiS), nickel phosphide (NiP) and nickel carbide (NiC) was investigated for hydrotreating of spent coffee oil to produce bio-hydrotreated fuel (BHF). The condition of hydrotreating was performed at a 375-425 °C, 20-40 bar of initial H<sub>2</sub> pressure (before heating) with a reaction time of 0–3 h. The activity of the catalysts decreases in the order of NiC > NiP > NiS. NiC tended to promote the cracking reaction, which high gasoline and gaseous yields. The decarbonylation (DCO) more than decarboxylation (DCO<sub>2</sub>) and hydrodeoxygenation (HDO) for deoxygenation of coffee oil for all the catalysts. The (DCO + DCO<sub>2</sub>) to HDO ratio decreased in the order NiS > NiC > NiP. Straight-chain hydrocarbons are the main products, which high cetane index (> 110).

Monnier et al. [43] studied hydrodeoxygenation of oleic acid and canola oil by molybdenum, tungsten and vanadium supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> were prepared by the temperature-programmed reaction. The condition of hydrodeoxygenation is performed at 380-410 °C and 7.15 MPa of hydrogen pressure. The result showed the molybdenum nitride catalyst high catalytic hydrotreating of oleic acid (in terms of fatty acid conversion, oxygen removal and production of normal alkanes) more than to the vanadium and tungsten nitrides catalyst. The dominant reaction pathways of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> supported molybdenum catalyst are hydrodeoxygenation while the decarbonylation and decarboxylation promoted to hydrocarbon of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> supported vanadium nitride catalyst. A 450 h hydrotreating test performed at 400 °C and 8.35 MPa hydrogen pressure of canola oil with Mo<sub>2</sub>N/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst indicated high oxygen removal throughout the test, which exceeds 90%.

Stefan et al. [36] studied the hydrodeoxygenation of oleic acid comparison between carbon nanofiber supported W<sub>2</sub>C and Mo<sub>2</sub>C catalysts. This research investigated activity, selectivity, and stability to evaluate the catalytic potential for the upgrading of fat/oil feeds. W<sub>2</sub>C/CNF catalyst was more selective toward olefins, whereas Mo<sub>2</sub>C/CNF catalyst was more selective toward paraffins. Mo<sub>2</sub>C/CNF catalyst showed higher activity and stability compared with W<sub>2</sub>C/CNF catalyst. The metal carbide catalyst promoted hydrodeoxygenation of unsaturated fatty acids. The olefinic products of W<sub>2</sub>C/CNF catalyst higher than Mo<sub>2</sub>C/CNF catalyst, which resulted in a higher deactivation rate of the tungsten-based catalyst. In addition, W<sub>2</sub>C/CNF catalyst presented more sensitivity to oxidation compared with Mo<sub>2</sub>C/CNF catalyst. W<sub>2</sub>C/CNF catalyst is shown more suitable for production as a high value olefinic product. on the other hand, Mo<sub>2</sub>C/CNF catalyst shows increased activity and catalyst stability more than Mo<sub>2</sub>C/CNF catalyst.

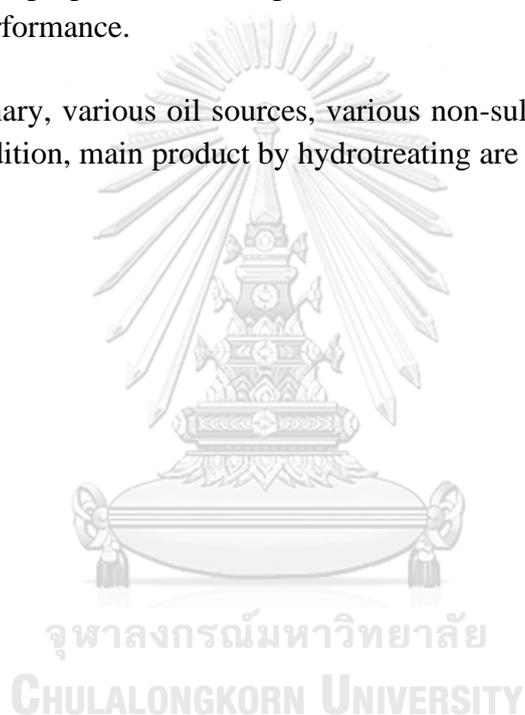

Wang et al. [44] studied the diesel-like hydrocarbons production via the hydrotreatment of fatty acids using activated carbon-supported  $\text{Mo}_2\text{C}$  and  $\text{W}_2\text{C}$  catalysts under  $360\text{ }^\circ\text{C}$  of temperature,  $3.0\text{ MPa}$  of hydrogen pressure and  $3.0\text{ h}$  of reaction time. The result showed that high carburization temperature was feasible for  $\text{W}_2\text{C}/\text{AC}$  catalyst, but not for  $\text{Mo}_2\text{C}/\text{AC}$  catalyst because it resulted in an agglomeration of molybdenum compound and destruction of catalyst. The high reaction temperature highly improved the conversion over  $\text{Mo}_2\text{C}/\text{AC}$  catalyst and  $\text{W}_2\text{C}/\text{AC}$  catalyst during hydrotreatment of fatty acid. The conversion of  $\text{Mo}_2\text{C}/\text{AC}$  catalyst prepared at  $700\text{ }^\circ\text{C}$  and  $\text{W}_2\text{C}/\text{AC}$  catalyst prepared at  $900\text{ }^\circ\text{C}$  are  $96.01\%$  and  $54.88\%$ , respectively. The  $20\%$  loading of both  $\text{Mo}_2\text{C}/\text{AC}$  catalyst and  $\text{W}_2\text{C}/\text{AC}$  catalyst are the best metal loading due to high active sites and low agglomeration. Moreover, the high temperature promoted the cracking degree and DCO route. The proposed pathway of the hydrotreatment reaction of fatty acids to green diesel is shown in Figure 7.

**Figure 7** The proposed pathway of the hydrotreatment reaction of fatty acids to green diesel [44].

Phimsen et al. [45] studied the nickel-based carbide catalysts combined with Mo, Nb, W, and Zr on Al-SBA-15 support were investigated for the hydrocracking of distillers dried grains with soluble (DDGS) corn oil to produce biofuels under 400 °C of temperature and 4.48 MPa of hydrogen pressure. Interested, the effects of the fractional sums of the electronegativities of the transition metals on the catalyst activities, selectivity and liabilities. NiWC/Al-SBA-15 catalyst highest diesel selectivity with a fractional sum of electronegativity of 2.06. The NiNbC/Al-SBA-15 catalyst promoted with 5% Ce maintained stable activity for 168 h at 400 °C and 4.48 MPa hydrogen pressure. Adding Ce adjusting the combined electronegativities nearer to 2.0-2.2, which improved catalyst performance. On the other hand, adding Ce effected to textural properties, or the performance of individual metals could also impact catalyst performance.

As a summary, various oil sources, various non-sulfide catalysts type, reactor type, reaction condition, main product by hydrotreating are shown in Table 5.

**Table 5** The various non-sulfide catalyst type and reaction conditions of hydrotreating for product biofuel.

Item	Catalyst	Oil	Reactor	Condition	Main product	Performance	Ref.
1	Mo <sub>2</sub> C/RGO  Mo <sub>2</sub> C/AC	Oleic acid	Fixed bed reactor	T=350 °C P=5 MPa LSHV=2 h <sup>-1</sup> H <sub>2</sub> /oil ratio = 4.5 N(cm <sup>3</sup> ·cm <sup>-3</sup> )	C <sub>17</sub> -C <sub>18</sub> Hydrocarbon	Selectivity: 90 % Yield: 84.5 %  Selectivity: 60 % Yield: 50.3 %	[46]

## CHAPTER IV

### METHODOLOGY

#### 4.1 Chemicals

Table 6 lists the chemicals used in this study.

**Table 8** The details of chemicals used in this study

Chemicals	Formula	Purity	Manufacture
PFAD	-	-	Patum Vegetable Thailand
Ammonium molybdate	$(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$	81.0-83.0%	UNILAB
Nickel nitrate	$\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$	97.0%	UNILAB
Cobalt nitrate	$\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$	100%	Ajax Finechem
Hexamethylenetetramine	$\text{C}_6\text{H}_{12}\text{N}_4$	99.0%	Sigma Aldrich
Ammonia solution	$\text{NH}_4\text{OH}$	25%	ChemX
Aluminum oxide	$\gamma\text{-Al}_2\text{O}_3$	Assay 100%	Fluka
Hydrogen gas	$\text{H}_2$	99.9%	Linde
Nitrogen gas	$\text{N}_2$	99.9%	Linde

## 4.2 Catalyst preparation

### 4.2.1 Preparation of molybdenum nitride and carbide-based catalysts on $\gamma$ -Al<sub>2</sub>O<sub>3</sub> support by the single-step decomposition method

The  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> support was crushed and sieved to 0.45-1.00 mm particle size for all catalysts. A mixture for the Mo<sub>2</sub>N and Mo<sub>2</sub>C supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalysts were prepared by dissolving hexamethylenetetramine (HMTA) and ammonium heptamolybdate ((NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O) with a fixed molar ratio of 1:2, and a proper amount of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> in 15% ammonia solution. The solution was stirred for 24 h. at room temperature. The molybdenum content was fixed 20% by weight. In the case of bimetallic catalysts, the Mo<sub>3</sub>Ni<sub>3</sub>N, Mo<sub>3</sub>Ni<sub>3</sub>C, Mo<sub>3</sub>Co<sub>3</sub>N and Mo<sub>3</sub>Co<sub>3</sub>C supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalysts were prepared by dissolving ammonium heptamolybdate ((NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O), Nickel nitrate (Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O) or Cobalt nitrate (Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O) and hexamethylenetetramine (HMTA) with a fixed molar ratio of 2:14:34, and a proper amount of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> in 15% ammonia solution. The solution was stirred for 24 h. at room temperature. The metal content was fixed 20% by weight. Then Ni<sub>3</sub>Mo<sub>3</sub>X and Co<sub>3</sub>Mo<sub>3</sub>X support on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> by were prepared by impregnation method. After impregnation, all catalysts were dried for an overnight at 120°C. The resultant samples were activated under flowing nitrogen (nitride forms) and hydrogen (carbide forms) at a heating rate of 3 °C min<sup>-1</sup> to 700 °C for 3 h. Finally, the carbide and nitride catalysts were cooled to room temperature in nitrogen and hydrogen, respectively.

### 4.2.2 Preparation of molybdenum carbide-based catalysts by temperature-programmed reduction (TPR) method

The  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> support was crushed and sieved to 0.45-1.0 mm particle size for all catalysts. The  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> supported Ni<sub>3</sub>Mo<sub>3</sub>C and Co<sub>3</sub>Mo<sub>3</sub>C catalysts were prepared by co-impregnation. First, NiMo and CoMo were supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> by impregnating of an aqueous solution of ammonium heptamolybdate ((NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O) and Nickel nitrate (Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O) or Cobalt nitrate (Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O). Then, the sample was dried overnight at 120 °C and calcined at 500 °C for 5 h. to obtain the  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> supported metal oxide catalysts with the metal loading of 20 wt.%. The resultant samples were activated under 20%CH<sub>4</sub>/H<sub>2</sub> at a heating rate of 10 °C min<sup>-1</sup> to 250 °C, then heated up to 700 °C for half an hour to obtain Ni<sub>3</sub>Mo<sub>3</sub>C/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> and Co<sub>3</sub>Mo<sub>3</sub>C/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalysts. Finally, the supported bimetallic carbide catalysts were cooled to room temperature.

### 4.3 Catalyst characterizations

#### 4.3.1 X-ray diffraction

The crystal structure and phase of the prepared catalysts were analyzed by X-ray diffraction (XRD, Bruker of D8 Advance) using Cu K $\alpha$  source,  $2\theta$  in range of  $20^\circ$  to  $80^\circ$ .

#### 4.3.2 X-ray photoelectron spectroscopy

To determine the type of metal carbide, nitride and oxides species on the surface layer of catalysts were performed using the Kratos Amicus x-ray photoelectron spectroscopy (XPS) spectra, which worked at a power of 240 W with the x-ray source at 20 mA. The survey spectra were recorded using a pass energy of 75 eV and a step size of 0.1 eV/step under pressure about  $1 \times 10^{-6}$  Pa.

#### 4.3.3 N<sub>2</sub> Sorption

The specific surface area, pore-volume, and pore size diameter of catalyst were determined from the N<sub>2</sub> adsorption-desorption isotherms by use a BEL SORP mini II device.

#### 4.3.4 Scanning electron microscopy and Energy-dispersive x-ray spectroscopy (SEM and EDX)

Morphology and elemental distribution of prepared catalysts were analyzed by scanning electron microscopy and Energy-dispersive x-ray spectroscopy (SEM and EDX, Hitachi mode S-3400N for SEM while Link Isis series 300 program for EDX).

#### 4.3.5 Thermogravimetric analysis

The carbon deposited on catalyst was measured by thermogravimetric analysis (TGA). The sample was heated up to  $1000^\circ\text{C}$  with the ramp rate of  $10^\circ\text{C min}^{-1}$  for measuring weight loss of spent catalysts.

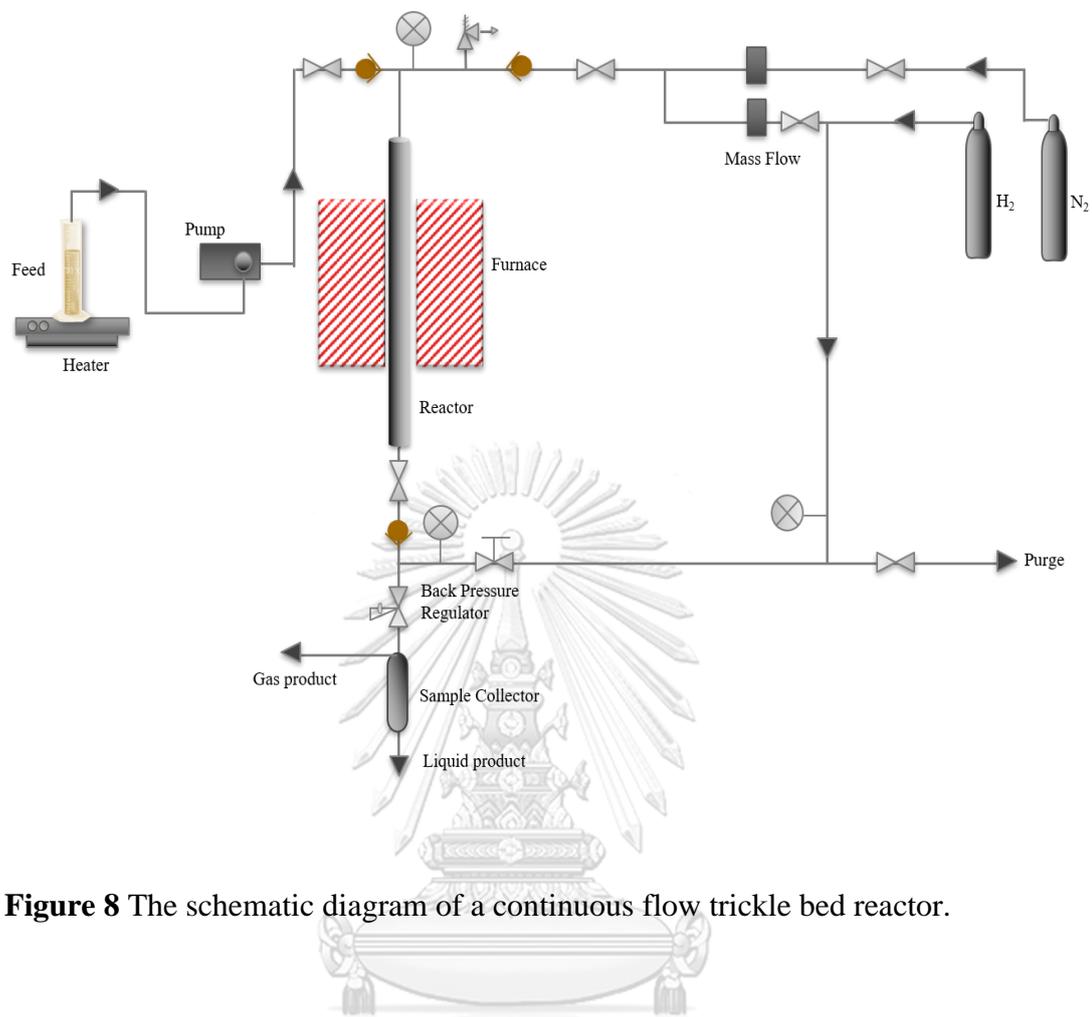

## 4.4 Catalytic deoxygenation test

### 4.4.1 Pre-reduction process

After activation, the carbide and nitrite catalysts were removed from the quartz tube. The carbide and nitride catalysts were reduced under  $100 \text{ ml min}^{-1}$  of hydrogen flow at a heating rate of  $5 \text{ }^\circ\text{C min}^{-1}$  from room temperature to  $450 \text{ }^\circ\text{C}$  for 3 h. before the reaction test.

### 4.4.2 Activity test

The bio-hydrogenated diesel was carried out in a continuous flow trickle-bed reactor with a length of 50 cm and an inside diameter of 0.9 cm. The schematic diagram of the experimental equipment is shown in Figure 8. The catalyst with a volume of 6 ml was loaded into the reactor. All the catalysts were stabilized under operating conditions for 24 h. on stream. The operating conditions for the optimal operating conditions are shown in Table 7-10. The palm fatty acid distillate (PFAD) was preheated and feed to a continuous flow trickle-bed reactor controlled by a high-pressure pump and hydrogen flow rate was controlled by the mass flow controller.

**Figure 8** The schematic diagram of a continuous flow trickle bed reactor.

#### 4.4.3 FT-IR

The functional group of palm fatty acid distillate (PFAD) and liquid products were measured by the Fourier transform infrared (FTIR) spectroscopy (Perkin Elmer spectrum GXFT-IR).

#### 4.4.4 Analysis of liquid and gas products

The liquid product and gaseous product were collected every 3 intervals. The gas product was analyzed by gas chromatography (GC, Shimadzu model GC-14B) equipped with thermal conductivity detector (TCD). The liquid product was analyzed gas chromatography equipped with flame ionization detector (FID). The operating conditions for the instruments are shown in Table 11-12. The conversion, gasoline selectivity, diesel selectivity, gasoline yield and diesel yield of the products were determined by the following Equations (1)–(4) and (5), respectively.

$$\text{Conversion}(-) = \frac{\text{Feed}_{\text{FA+TG}} - \text{Product}_{\text{FA+TG}}}{\text{Feed}_{\text{FA+TG}}} \quad (1)$$

$$\text{Gasoline selectivity}(-) = \frac{\text{Product}_{\text{C}_5\text{-C}_{11}} - \text{Feed}_{\text{C}_5\text{-C}_{11}}}{\text{Feed}_{\text{FA+TG}} - \text{Product}_{\text{FA+TG}}} \quad (2)$$

$$\text{Diesel selectivity}(-) = \frac{\text{Product}_{\text{C}_{12}\text{-C}_{18}} - \text{Feed}_{\text{C}_{12}\text{-C}_{18}}}{\text{Feed}_{\text{FA+TG}} - \text{Product}_{\text{FA+TG}}} \quad (3)$$

$$\text{Gasoline yield} = \text{liquid fraction} \times \text{conversion} \times \text{gasoline selectivity} \quad (4)$$

$$\text{Diesel yield} = \text{liquid fraction} \times \text{conversion} \times \text{diesel selectivity} \quad (5)$$

Where

$\text{Feed}_{\text{FA+TG}}$  is the weight percent of fatty acid and triglyceride in Feed.

$\text{Product}_{\text{FA+TG}}$  is the weight percent of fatty acid and triglyceride in product

$\text{Feed}_{\text{C}_5\text{-C}_{11}}$  and  $\text{Product}_{\text{C}_5\text{-C}_{11}}$  are the percent of alkanes at a boiling point in the range of  $\text{C}_5\text{-C}_{11}$  in feed and product, respectively.

$\text{Feed}_{\text{C}_{12}\text{-C}_{18}}$  and  $\text{Product}_{\text{C}_{12}\text{-C}_{18}}$  are the percent of alkanes at a boiling point in the range of  $\text{C}_{12}\text{-C}_{18}$  in feed and product, respectively. Gas and liquid fraction can be calculated from equations (6) and (7), respectively.

$$\text{Liquid fraction} = \frac{\text{weight of liquid product}}{\text{weight of feed}} \quad (6)$$

$$\text{Gas fraction} = 1 - \frac{\text{weight of liquid product}}{\text{weight of feed}} \quad (7)$$

Where

Gasoline yield = liquid fraction x conversion x gasoline selectivity

Diesel yield = liquid fraction x conversion x diesel selectivity

Yield of liquid fuel = diesel yield + gasoline yield

#### 4.4.5 The maximum theoretical yields

The maximum theoretical yields of deoxygenated products were calculated based on the compositions of 6.8 wt.% of triglyceride and 93.2 wt.% of fatty acid contained in PFAD (See Table 1). The maximum theoretical yields of HDO and DCO<sub>x</sub> (DCO+DCO<sub>2</sub>) reaction pathway were determined by the following Equations (8) and (9), respectively.

$$\text{The maximum theoretical yields of HDO} = \text{HDO (FFA)} + \text{HDO (TG)} \quad (8)$$

$$\text{The maximum theoretical yields of DCO}_x = \text{DCO}_x \text{ (FFA)} + \text{DCO}_x \text{ (TG)} \quad (9)$$

Where

$$\text{HDO (FFA)} = \frac{Mw_{C_nH_{2n+2}}}{Mw_{\text{fatty acid}}} \times \% \text{ FFA distribution in PFAD} \times 93.2 \% \text{ of FFA}$$

$$\text{HDO (TG)} = \frac{Mw_{C_nH_{2n+2}}}{Mw_{\text{triglyceride}}} \times \% \text{ FFA distribution in PFAD} \times 6.8 \% \text{ of TG}$$

$$\text{DCO}_x \text{ (FFA)} = \frac{Mw_{C_nH_{2n+2}}}{Mw_{\text{fatty acid}}} \times \% \text{ FFA distribution in PFAD} \times 93.2 \% \text{ of FFA}$$

$$\text{DCO}_x \text{ (TG)} = \frac{Mw_{C_nH_{2n+2}}}{Mw_{\text{triglyceride}}} \times \% \text{ FFA distribution in PFAD} \times 6.8 \% \text{ of TG}$$

**Table 13** Operating condition in Gas Chromatography – Flame Ionization Detector (GC-FID).

## CHAPTER V

### RESULTS AND DISCUSSION

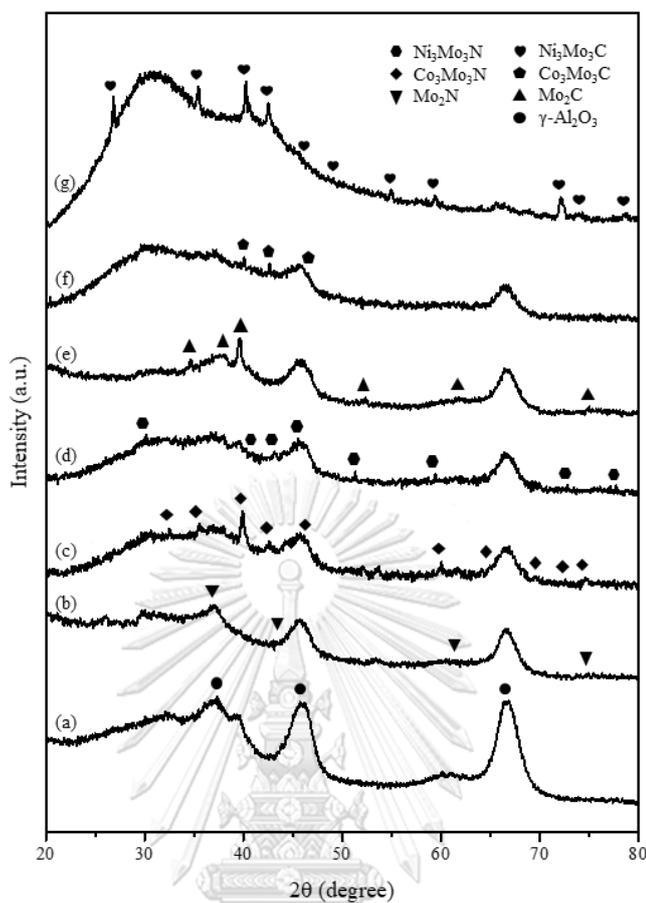

This chapter is divided into three main parts. In the first part, catalyst screening among carbide and nitride catalysts was investigated. The catalysts preparation was compared between a single-step decomposition method and the temperature-programmed reduction (TPR). In the second part, the effects of operating temperature and hydrogen pressure on the conversion, selectivity, yield, gas product composition and contribution of HDO and DCO<sub>x</sub> were investigated.

#### 5.1 Catalyst screening and comparison of bimetallic carbide catalysts

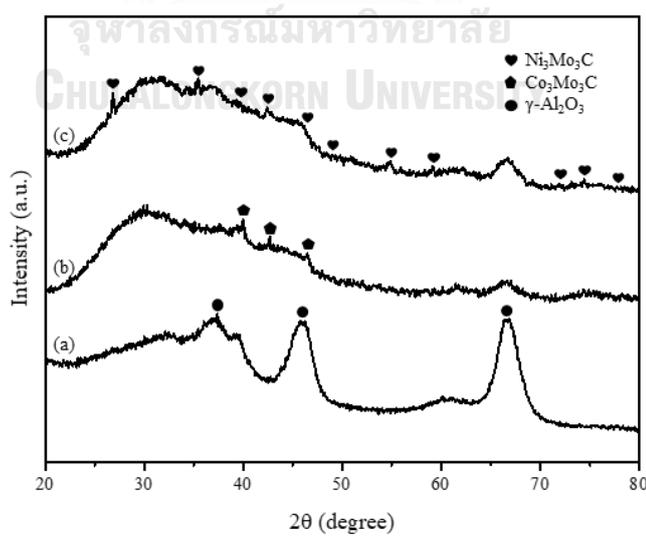

##### 5.1.1 Catalyst characterization

###### 5.1.1.1 X-ray diffraction (XRD)

The XRD patterns of the alumina-supported metal nitride catalysts are shown in Fig. 9. The diffraction peaks of cubic  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> at 37.5°, 46° and 67° were detected for all the catalysts [48-50]. The diffraction peaks of Mo<sub>2</sub>N phase at 37.2°, 43.3°, 62.8°, and 75.4° for the Mo<sub>2</sub>N supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst could not be detected due to overlapping with peaks of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> support [51, 52]. The diffraction peak at 32.50°, 35.54°, 40.10°, 42.63°, 46.63°, 59.99°, 65.01°, 69.89°, 72.79° and 74.57° were attributed to the Co<sub>3</sub>Mo<sub>3</sub>N phase [51]. The peak at 30.22°, 40.92°, 43.32°, 45.46°, 51.65°, 59.18°, 72.81° and 77.74° were attributed to the Ni<sub>3</sub>Mo<sub>3</sub>N phase [51]. The XRD patterns of the alumina-supported metal carbide catalysts are shown in Figs. 9 and 10. In addition, the diffraction peaks at 34.7°, 38.0°, 39.8°, 52.26°, 62.1°, and 75.5° were assigned to Mo<sub>2</sub>C phase observed in the Mo<sub>2</sub>C supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst [52]. The diffraction peaks at 39.9°, 42.6° and 46.5° attributed to the Co<sub>3</sub>Mo<sub>3</sub>C phase for the Co<sub>3</sub>Mo<sub>3</sub>C supported on  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> catalyst could not be detected due to overlapping with peaks of  $\gamma$ -Al<sub>2</sub>O<sub>3</sub> support [44, 53]. The observed diffraction peaks at (d) graph were assigned to Ni<sub>3</sub>Mo<sub>3</sub>C phase (JCPDS no. 89-4883) [54].

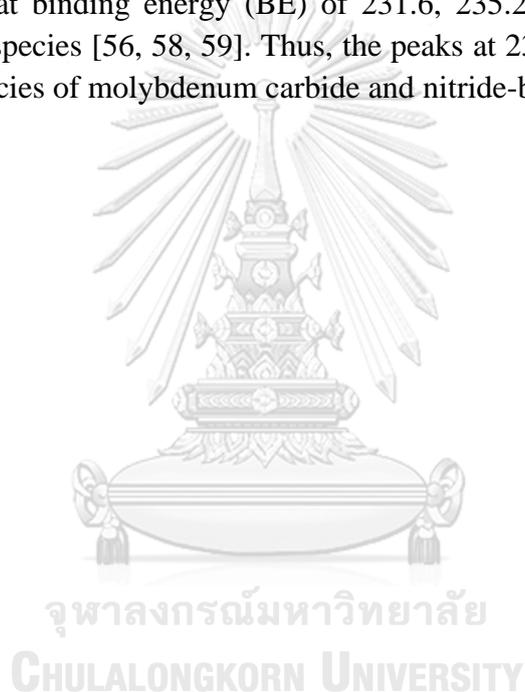

**Figure 9** XRD patterns of the (a)  $\gamma\text{-Al}_2\text{O}_3$  Support, (b)  $\text{MoN/Al}$ , (c)  $\text{CoMoN/Al}$ , (d)  $\text{NiMoN/Al}$ , (e)  $\text{MoN/Al}$ , (f)  $\text{CoMoC/Al}$ , and (g)  $\text{NiMoN/Al}$  catalysts.

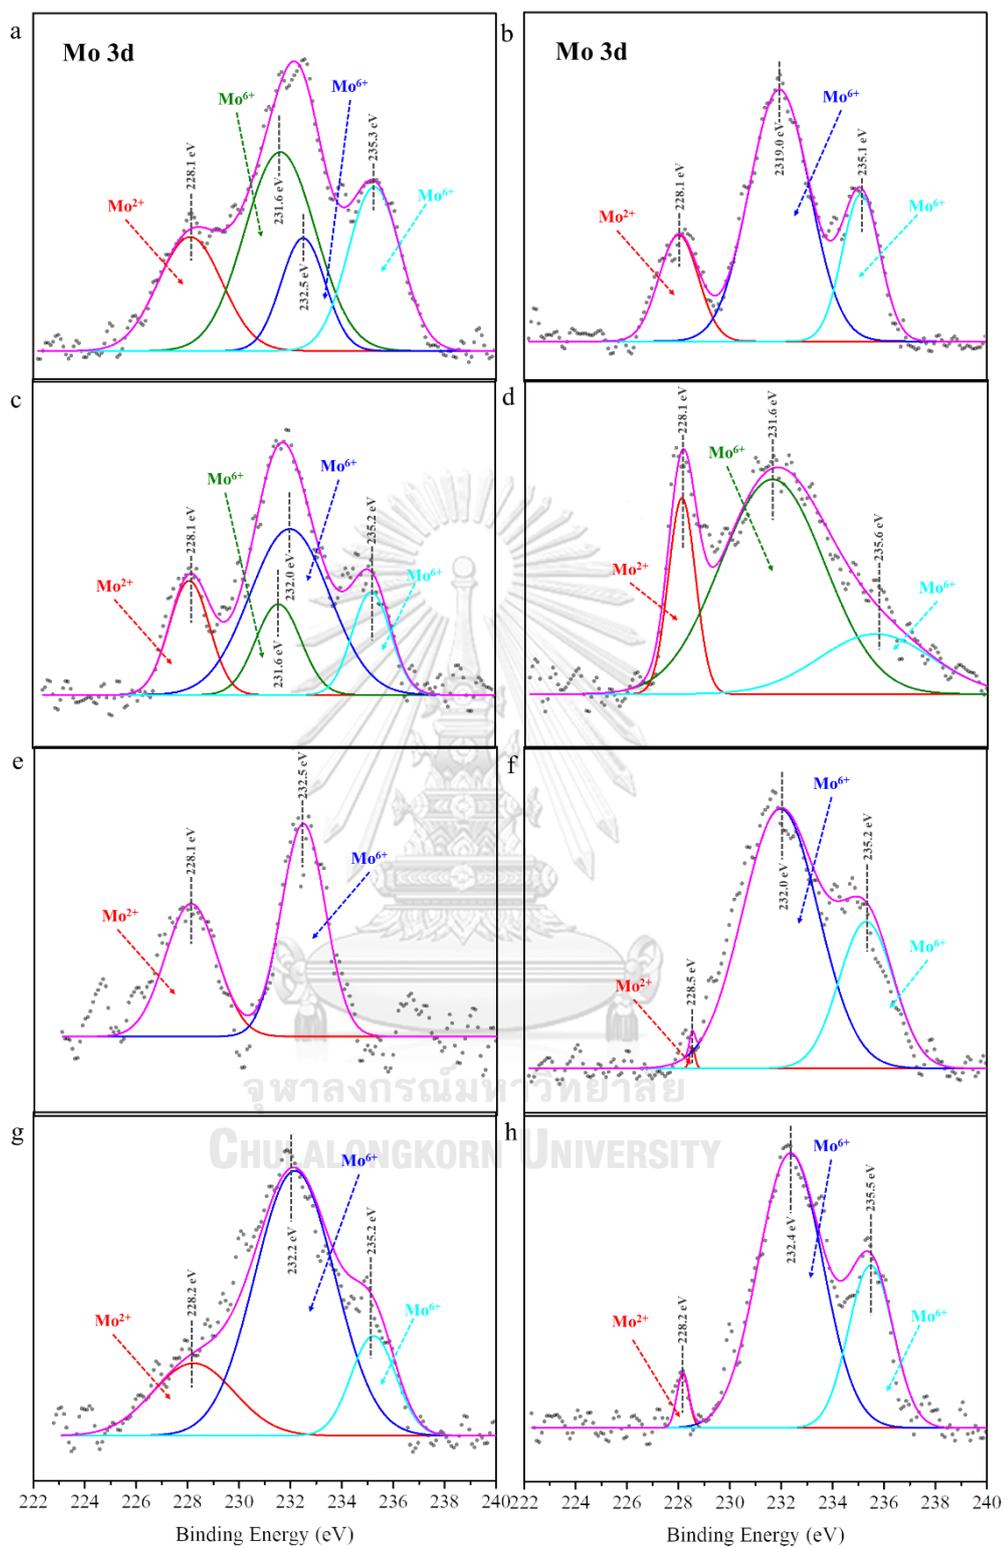

**Figure 10** XRD patterns of the (a)  $\gamma\text{-Al}_2\text{O}_3$  Support, (b)  $\text{CoMoC/Al}$  catalysts (TPR method), and (c)  $\text{NiMoC/Al}$  catalysts (TPR method).

### 5.1.1.1 X-ray photoelectron spectroscopy (XPS)

The XPS spectra of (a) MoC/Al, (b) CoMoC/Al, (c) NiMoC/Al, (d) CoMoC/Al-TPR, (e) NiMoC/Al-TPR, (f) MoN/Al, (g) NiMoN/Al and (h) CoMoN/Al catalysts are shown in Figure 11. The Mo  $3d_{5/2}$  spectra at binding energy (BE) of 228.1, 228.4 and 228.5 eV are assigned to  $Mo^{2+}$  species [55-58]. While the Mo  $3d_{3/2}$  spectra at binding energy (BE) of 231.9 eV are assigned to  $Mo^{2+}$  species [56]. Thus, the peak at  $228.2 \pm 0.2$  eV and 231.9 eV are ascribed to  $Mo^{2+}$  involved in Mo-C and M-N bonding of molybdenum carbide and nitride-based catalysts. The peak located at 232.0, 232.2, 232.5 and 232.9 eV were detected in Mo oxide phase corresponds to Mo  $3d_{5/2}$  of  $Mo^{6+}$  species due to oxidation of catalyst surface [51, 56, 57, 59]. In addition, Mo  $3d_{3/2}$  spectra at binding energy (BE) of 231.6, 235.2, 235.5 and 235.7 eV are assigned to  $Mo^{6+}$  species [56, 58, 59]. Thus, the peaks at 231.6,  $232.4 \pm 5$  and  $235.2 \pm 4$  represent  $Mo^{6+}$  species of molybdenum carbide and nitride-based catalysts.

**Figure 11** Mo3d spectra of (a) MoC/Al, (b) CoMoC/Al, (c) NiMoC/Al, (d) CoMoC/Al-TPR, (e) NiMoC/Al-TPR, (f) MoN/Al, (g) CoMoN/Al and (h) NiMoN/Al catalysts.

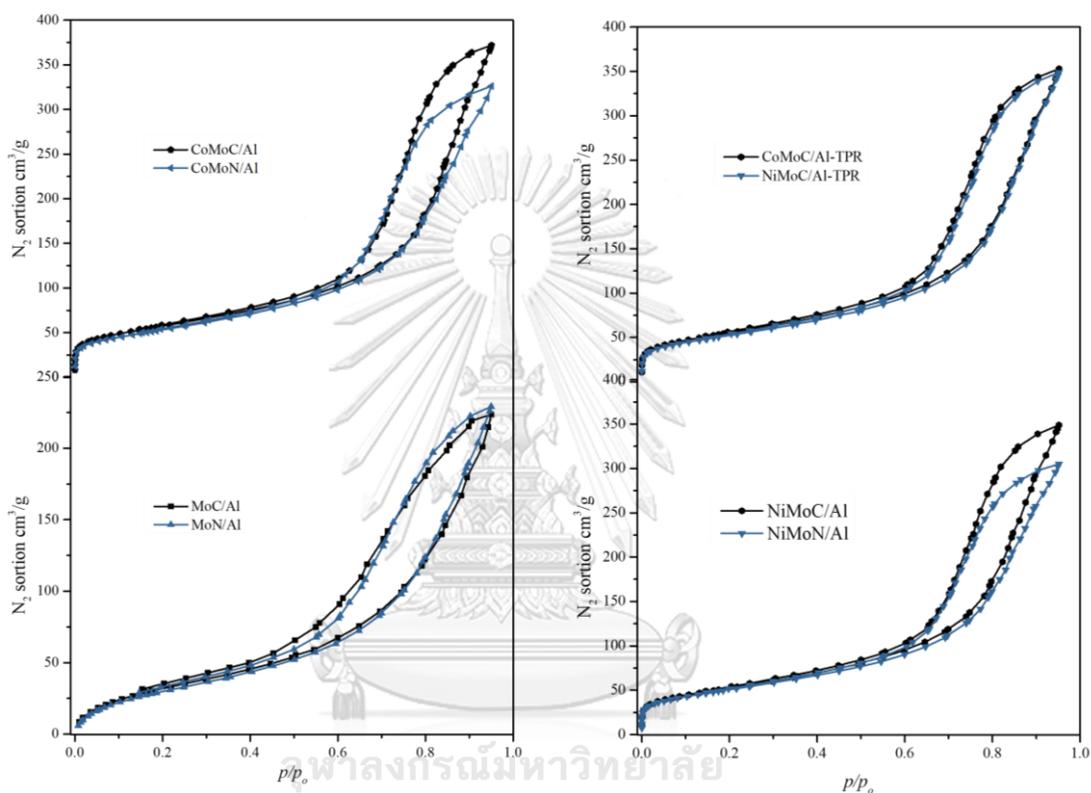

5.1.1.2 N<sub>2</sub> Physisorption**Table 15** Physical properties of the fresh catalysts.

Catalysts	Surface area (m <sup>2</sup> ·g <sup>-1</sup> )	Total pore volume (cm <sup>3</sup> ·g <sup>-1</sup> )	Mean pore diameter (nm)
γ-Al <sub>2</sub> O <sub>3</sub>	232	0.73	12.58
MoC/Al	123	0.35	11.22
MoN/Al	121	0.35	11.75
CoMoC/Al	193	0.58	11.95
CoMoN/Al	186	0.50	10.82
NiMoC/Al	179	0.54	12.05
NiMoN/Al	171	0.47	11.04
CoMoC/Al-TPR	190	0.55	11.43
NiMoC/Al-TPR	172	0.49	11.74

Table 13 summarizes the BET specific surface areas, total pore and means pore diameter of MoC/Al, MoN/Al, CoMoC/Al, CoMoN/Al, NiMoC/Al, NiMoN/Al CoMoC/Al-TPR and NiMoC/Al-TPR catalysts. The BET specific surface areas and total pure volume increased in the order of CoMoC/Al > CoMoC/Al-TPR > CoMoN/Al > NiMoC/Al > NiMoC/Al-TPR > NiMoN/Al > MoC/Al > MoN/Al catalysts.

The BET specific surface area and total pore volume of the γ-Al<sub>2</sub>O<sub>3</sub> support decreased with metal loading of Mo, Co and Ni species. As a result of the pore structure of pure γ-Al<sub>2</sub>O<sub>3</sub> support was filled or blocked by metals (Mo, Co and Ni) species. In contrast, average pore diameter of all the catalyst did not significantly change after impregnation of metal species.

$N_2$  adsorption/desorption isotherm of fresh catalysts are shown in Figure 12. The  $N_2$  adsorption/desorption isotherm of all the catalysts show type IV adsorption isotherms, indicating the mesoporous structure of all  $\gamma-Al_2O_3$  supported catalysts. Moreover, the area of the hysteresis loop of MoC/Al and MoN/Al catalysts was decreased, indicating that the pores of catalysts were blocked by Mo species [60, 61]. These were consistent with the BET specific surface area and total pore volume of both catalysts (See Table 13).

**Figure 12**  $N_2$  adsorption/desorption isotherm of MoC/Al, MoN/Al, CoMoC/Al, CoMoN/Al, NiMoC/Al and NiMoN/Al catalysts.

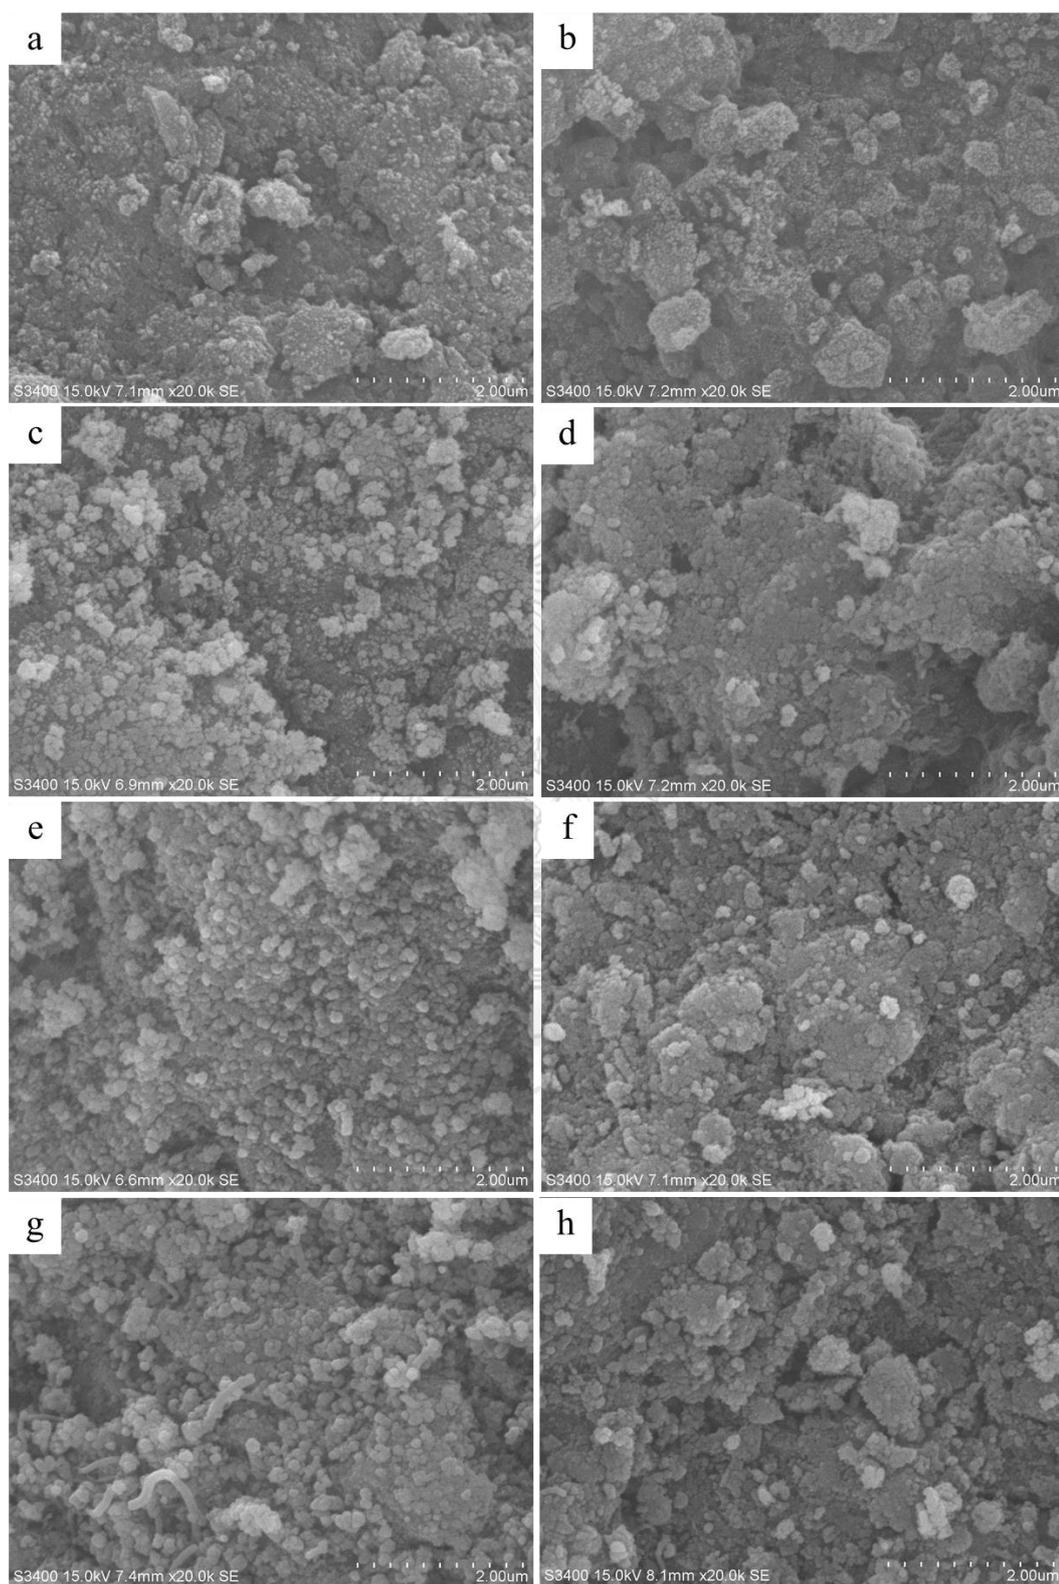

### 5.1.1.3 Scanning electron microscopy and Energy-dispersive x-ray spectroscopy (SEM and EDX)

**Table 16** Elemental distribution of the fresh catalysts.

Catalysts	Elements (wt.%)							
	Mo	Al	O	Co	Ni	C	N	Mo/Metal
MoC/Al	19.9	47.4	28.9	-	-	3.3	0.6	-
MoN/Al	19.5	45.8	30.6	-	-	2.9	1.2	-
CoMoC/Al	12.9	47.5	28.4	7.3	-	3.1	0.9	1.1
CoMoN/Al	12.7	45.5	28.8	7.2	-	4.0	1.9	1.1
NiMoC/Al	12.3	46.7	29.4	-	7.4	3.8	0.7	1.0
NiMoN/Al	12.3	45.5	28.7	-	7.6	3.8	1.2	1.0
CoMoC/Al-TPR	13.1	45.9	27.9	8.5	-	4.6	0.0	0.9
NiMoC/Al-TPR	12.7	46.1	29.1	-	7.4	4.8	0.0	1.1

The fresh catalysts were characterized by energy-dispersive x-ray spectroscopy (EDX) to examine metal content in catalysts. The elemental contents of the fresh catalysts are summarized in Table 14. It was found that metal content in catalysts was 20% according to percent loading in catalyst preparation. The mole of Mo to Co or Ni was 1:1, which corresponded to the equivalent mole of the metal in the catalyst preparation.

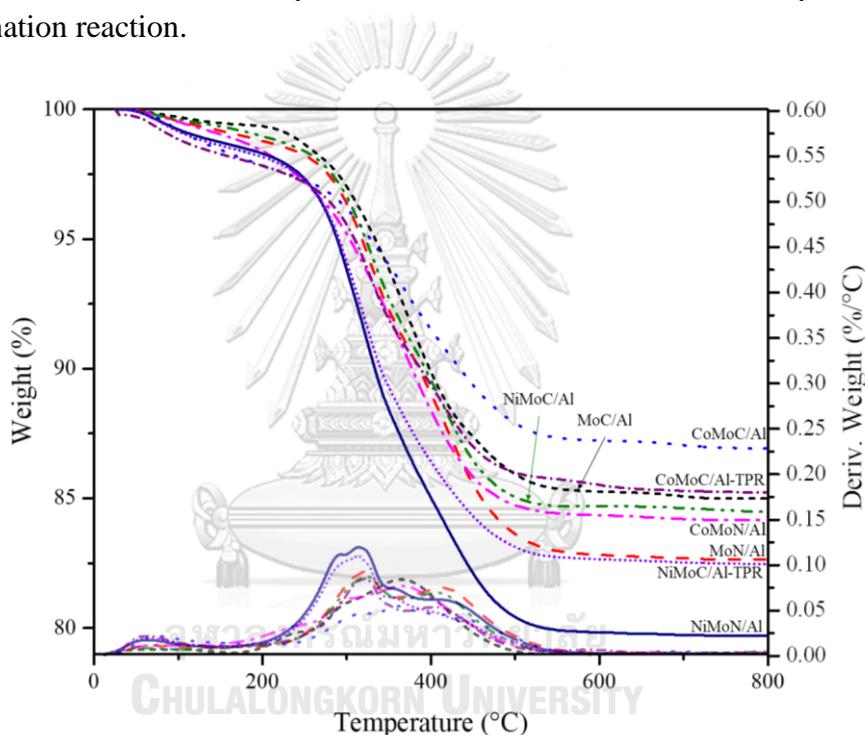

The SEM images of (a) MoC/Al, (b) MoN/Al, (c) CoMoC/Al, (d) CoMoN/Al, (e) NiMoC/Al, (f) NiMoN/Al, (g) CoMoC/Al-TPR and (h) NiMoC/Al-TPR catalysts are shown in Figure 13. The SEM images of MoC/Al and MoN/Al catalysts (Figure 12a and b) exhibited an agglomerated angular particles [51]. The addition of Co and Ni slightly changed the structures of the catalysts. The SEM images of CoMoC/Al, CoMoN/Al, NiMoC/Al, NiMoN/Al, CoMoC/Al-TPR, and NiMoC/Al-TPR catalysts (Figure 12c-h) indicated irregular particles with a size of 0.1-0.2  $\mu\text{m}$  [62, 63].

**Figure 13** SEM images of (a) MoC/Al, (b) MoN/Al, (c) CoMoC/Al, (d) CoMoN/Al, (e) NiMoC/Al, (f) NiMoN/Al, (g) CoMoC/Al-TPR and (h) NiMoC/Al-TPR catalysts.

#### 5.1.1.4 Thermogravimetric analysis (TGA)

The TGA profiles of spent catalysts after the hydrotreating of PFAD are exhibited in Figure 14. The weight loss with increasing temperature consists of three-stages at a temperature of 50 °C to 250 °C, 250 °C to 350 °C, and 350 °C to 600 °C, which corresponded to the loss of moisture, physical absorbents, and formation of coke (soft and hard), respectively [64]. The total weight loss was 12.8%, 14.2%, 14.7%, 15.3%, 15.7%, 17.1%, 17.3% and 20.2% for the CoMoC/Al, CoMoC/Al-TPR, MoC/Al, NiMoC/Al, MoN/Al, CoMoN/Al, NiMoC/Al-TPR, and NiMoN/Al catalysts, respectively. The amount of carbon deposition of nitride catalysts was higher than that of carbide catalysts of the deactivation of nitride catalysts during the deoxygenation reaction.

**Figure 14** TG/DTG profiles of the spent catalysts. The operating condition at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

### 5.1.2 Catalysis screening

This section studied the effect of metal loading for the Mo carbide and nitride catalysts. Excellent catalysts in carbide and nitride phases were selected for further optimization on the operation conditions and catalytic stability test.

**Table 17** Catalytic actives for deoxygenation of palm fatty acid distillate over carbide and nitride catalysts.

Catalysts	Conversion (%)	Selectivity (%)		Yield (%)		Product phase	Product color
		Diesel selectivity	Gasoline selectivity	Diesel yield	Gasoline yield		
MoC/Al	71	99.5	0.5	56.4	0.3	Solid+ Liquid	Light brown
MoN/Al	40	99.3	0.7	32.2	0.2	Solid	Light brown
CoMoC/Al	98	99.3	0.7	84.8	0.6	Liquid	Clear
CoMoN/Al	94	98.8	1.2	67.1	0.8	Liquid	Yellow
NiMoC/Al	98	99.6	0.4	78.1	0.3	Liquid	Clear
NiMoN/Al	73	99.4	0.6	61.8	0.4	Solid+ Liquid	Light brown

The catalytic actives for deoxygenation of palm fatty acid distillate over carbide and nitride catalysts. are summarized in Table 15 and the conversion and diesel yield are shown in Figure 15a. All supported catalysts (MoC/Al, MoN/Al, CoMoC/Al, CoMoN/Al, NiMoC/Al and NiMoN/Al) were investigated to examine the activity of the catalyst on deoxygenation reaction under a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

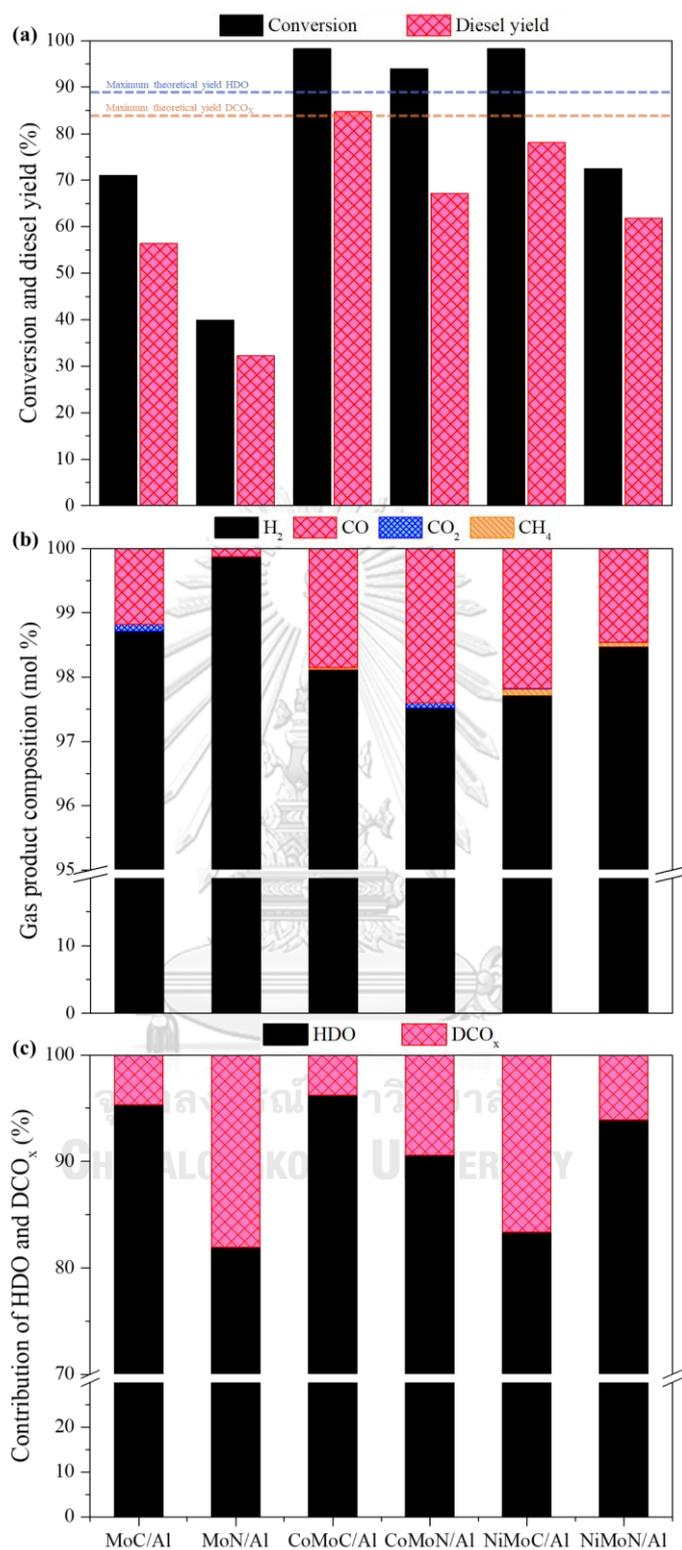

In case of the monometallic catalysts, MoC/Al catalyst exhibited the highest conversion in compared with the MoN/Al catalyst. This result was in agreement with those of Akhmetzyanova et al. [65] and Carmona et al. [66]. A comparison between monometallic and bimetallic carbide and nitride catalysts showed the difference in activity. Bimetallic carbide catalysts showed the highest conversion and diesel yield of 73% to 98% and 61.8% to 84.8%, respectively. In contrast, conversion and diesel yield of monometallic carbide and nitride catalysts were in the ranges of 40% to 71%

and 32.2% to 56.4%, respectively. These results were consistent with those of preceding studies [67, 68]. CoMoC/Al catalyst showed the highest conversion and diesel yield of 98% and 84.8%, respectively. CoMoN/Al catalyst showed the highest conversion and diesel yield in the nitride phase of 94% and 67.1%, respectively. Product phase of MoC/Al, MoN/Al, and NiMoN/Al catalyst showed solid phase as a result of low PFAD conversion. Moreover, product color corresponded to the activity of catalysts. High conversion and diesel yield of the product are a clear color similar to diesel petroleum fuel.

The maximum theoretical yields of deoxygenated products were calculated based on the compositions of 93.2 wt.% of fatty acid and 6.8 wt.% of triglyceride contained in PFAD are shown in figure 15a. The maximum theoretical yields were 83.7% and 88.9% of DCO<sub>x</sub> and HDO reaction pathways, respectively.

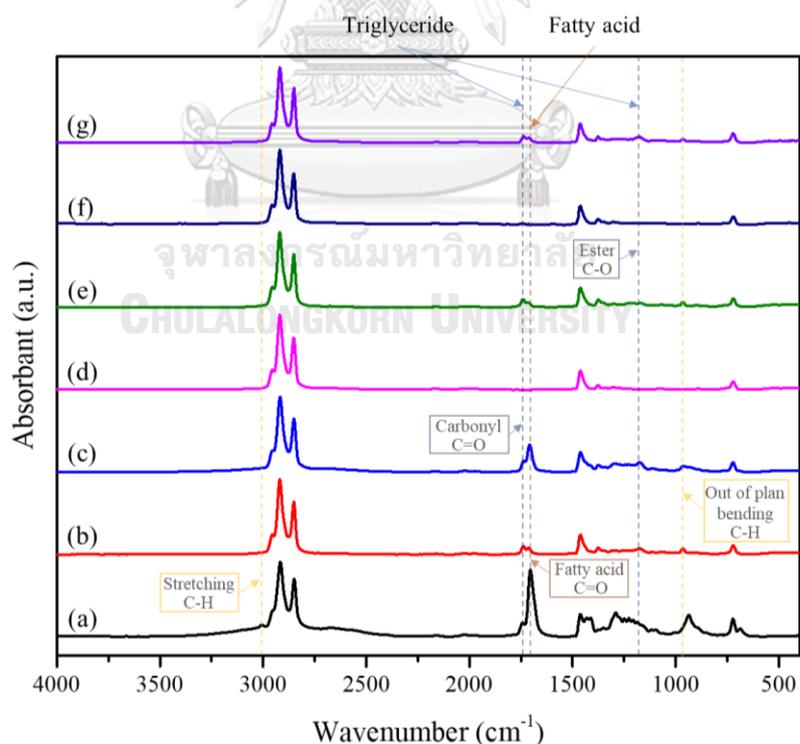

The Effect of catalysts on contribution of HDO and DCO<sub>x</sub> are shown in Figure 15c. All catalysts promote the hydrodeoxygenation (HDO) pathway, which consisted of high normal alkane of C<sub>14</sub>H<sub>30</sub>, C<sub>16</sub>H<sub>34</sub> and C<sub>18</sub>H<sub>38</sub>. The contribution of HDO decreased in order of CoMoC/Al > MoC/Al > NiMoC/Al > CoMoN/Al > NiMoC/Al > MoN/Al. HDO pathway could remove oxygen of free fatty acid in the form of water as a by-product. As a result, the number of carbon atom is same as the number of carbon atom in feedstock (oleic acid and palmitic acid mostly). On the other hand, decarboxylation (DCO<sub>2</sub>) and decarbonylation (DCO) pathway consisted of normal alkane of C<sub>15</sub>H<sub>32</sub> and C<sub>17</sub>H<sub>36</sub>. Contribution of DCO<sub>x</sub> decrease in order of MoN/Al > NiMoC/Al > CoMoN/Al > NiMoN/Al > MoC/Al > CoMoC/Al. While DCO<sub>x</sub> consists of DCO and DCO<sub>2</sub>. The DCO pathway could remove oxygen of free fatty acid and the carbon atom content in the feedstock in the form of CO. The DCO<sub>2</sub> pathway could remove oxygen of free fatty acid and the carbon atom content in the feedstock in the form of CO<sub>2</sub>. Therefore, the DCO pathway is the main pathway in %DCO<sub>x</sub> contribution because CO is mainly gas product compositions as shown in Figure 15b.

Gas product compositions are shown in Figure 15b. CO and CO<sub>2</sub> gas are by-product of DCO<sub>x</sub> pathway of deoxygenation reaction. While CH<sub>4</sub> generated by methanation of H<sub>2</sub> and CO<sub>2</sub> (Figure 5). Moreover, CO reacts with H<sub>2</sub>O to generate CO<sub>2</sub> by a water gas shift (Figure 5). Gas product compositions decreased in order to CoMoN/Al > NiMoC/Al > CoMoC/Al > NiMoN/Al > MoC/Al > MoN/Al, which relate to %DCO<sub>x</sub> contribution and PFAD conversion.

**Figure 15** Effect of catalysts on (a) conversion and diesel yield (b) gas product composition (c) liquid product composition and contribution of HDO and DCO<sub>x</sub> were performed at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

The functional group of the liquid products and feed characterized by Fourier transform infrared (FTIR) spectroscopy are shown in Figure 16. The triglyceride is represented by peaks at  $1746\text{ cm}^{-1}$  and  $1164\text{ cm}^{-1}$  which are corresponding to carbonyl group ( $\text{-C=O}$  stretch) and acid or ester groups ( $\text{-C-O}$  stretch), respectively [13]. Peak at  $1704\text{ cm}^{-1}$  corresponded to the carboxylic acid functional group of fatty acid detected in fatty acid [13, 69]. The aliphatic hydrocarbons generated from stretching, bending and rocking vibration of aliphatic hydrocarbons showed at  $3000\text{--}2800$ ,  $1465\text{--}1377$  and  $720\text{ cm}^{-1}$ , respectively. Peaks at  $3008$  and  $970\text{ cm}^{-1}$ , corresponded to  $\text{C-H}$  stretching and  $\text{C-H}$  out of plane bending, respectively [69]. Fatty acid and triglyceride peaks are represented in palm fatty acid distillate feedstock, which the fatty acid peak shows higher peak intensity than triglyceride peaks, represents high fatty acid content in PFAD. Fatty acid and triglyceride peaks were present in palm fatty acid distillate feedstock and they were absent in green diesel fuel spectrums. Because triglyceride and fatty acid were converted to green diesel fuel. Fatty acid and triglyceride peaks were not observed in  $\text{CoMoC/Al}$  and  $\text{NiMoC/Al}$  catalysts as they were completely converted to green diesel fuel. In contrast, Fatty acid and triglyceride peaks in the product present the incomplete conversion to green diesel fuel via the  $\text{MoC/Al}$ ,  $\text{MoN/Al}$ ,  $\text{CoMoN/Al}$  and  $\text{NiMoN/Al}$  catalysts. The FTIR results corresponded well with a conversion results of all catalysts (See Table 15).

**Figure 16** The FT-IR spectra of liquid products catalyzed by (a) PFAD, (b)  $\text{MoC/Al}$ , (c)  $\text{MoN/Al}$ , (d)  $\text{CoMoC/Al}$ , (e)  $\text{CoMoN/Al}$ , (f)  $\text{NiMoC/Al}$  and (g)  $\text{NiMoN/Al}$  catalysts.

### 5.1.3 Comparison of bimetallic carbide catalyst

In this section, the preparation of bimetallic carbide catalysts (CoMoC/Al and NiMoC/Al) was compared between the temperature-programmed reduction method (TPR) and the single-step decomposition method. The effect of the preparation method studied on conversion, selectivity, yield and reaction pathway (contribution of HDO and DCO<sub>x</sub>) were performed at a 330 °C of temperature, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

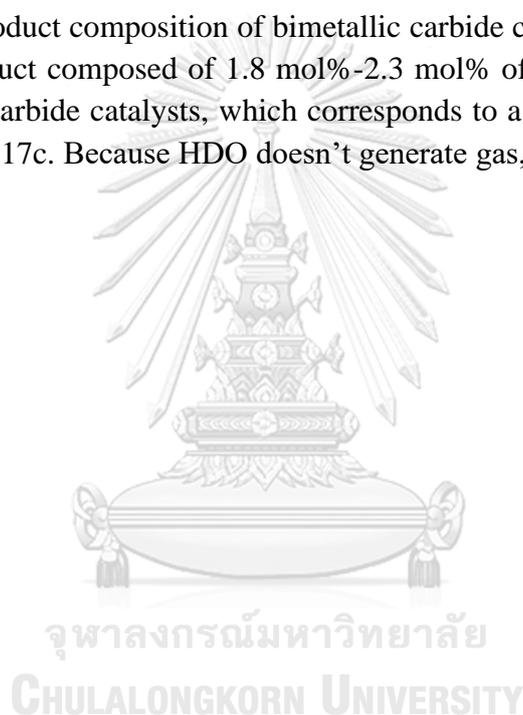

**Table 18** Effect of preparation method for bimetallic carbide catalysts on conversion, selectivity, yield, product phase and product color.

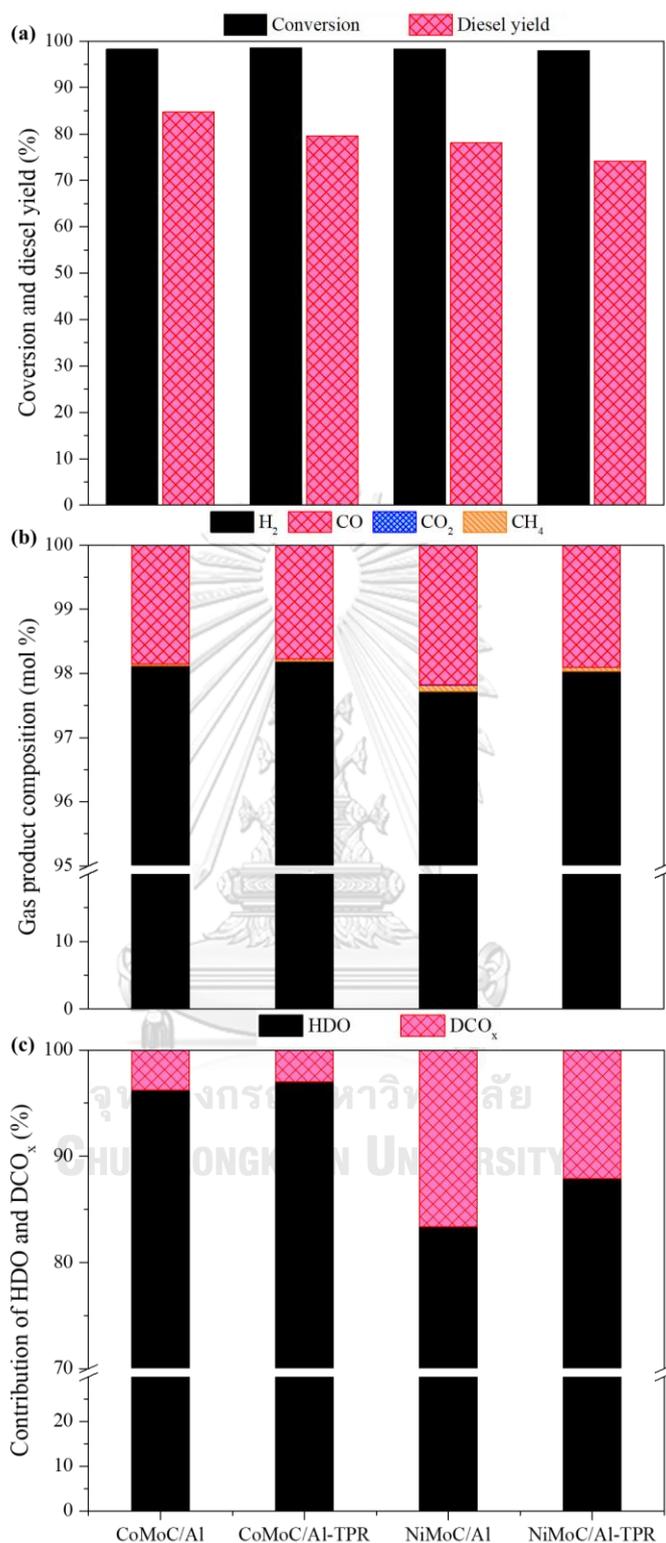

Catalysts	Conversion (%)	Selectivity (%)		Yield (%)		Product phase	Product color
		Diesel selectivity	Gasoline selectivity	Diesel yield	Gasoline yield		
CoMoC/Al	98	99.3	0.7	84.8	0.6	Liquid	Clear
CoMoC/Al-TPR	99	99.3	0.7	79.6	0.6	Liquid	Clear
NiMoC/Al	98	99.6	0.4	78.1	0.3	Liquid	Clear
NiMoC/Al-TPR	98	99.4	0.6	74.1	0.4	Liquid	Yellow

The effect of preparation method for bimetallic carbide catalysts on conversion, selectivity, yield, product phase and product color are summarized in Table 16. PFAD conversion and diesel yield are shown in Figure 17a. The deoxygenation of palm fatty acid distillate over CoMoC/Al and NiMoC/Al catalysts prepared by the single-step decomposition method and CoMoC/Al-TPR and NiMoC/Al-TPR prepared by catalysts by the temperature-programmed reduction method (TPR) were performed at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

The diesel yield of bimetallic carbide catalysts decreased in order to  $\text{CoMoC/Al} > \text{CoMoC/Al-TPR} > \text{NiMoC/Al} > \text{NiMoC/Al-TPR}$ . The bimetallic carbide catalysts prepared by the single-step decomposition method were slightly higher activity than the catalysts prepared by temperature-programmed reduction method (TPR). The single-step decomposition method (See Table 13) lead to higher larger pore volumes and surface areas, which improves the activity of the catalysts. That accorded the previous report on the comparison between the temperature-programmed reduction method and the single-step decomposition methods [62]. In addition, the single-step decomposition method is a simple method for the preparation of  $\text{CoMoC/Al}$  and  $\text{NiMoC/Al}$  catalysts.

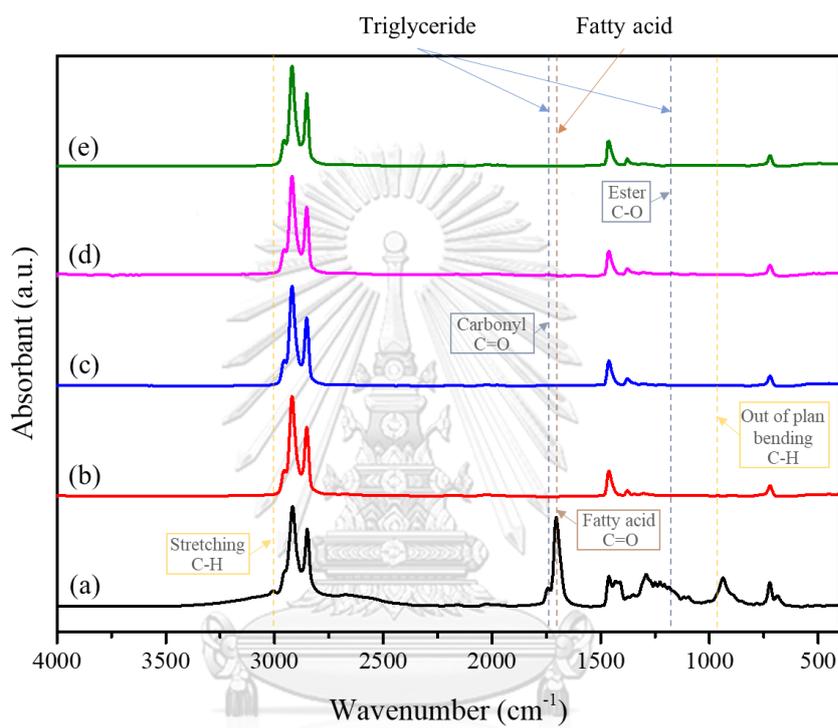

The gas product composition of bimetallic carbide catalysts is shown in Figure 17b. The gas product composed of 1.8 mol%-2.3 mol% of mixed  $\text{CO}$ ,  $\text{CO}_2$  and  $\text{CH}_4$  for all bimetallic carbide catalysts, which corresponds to a high contribution of HDO pathway in Figure 17c. Because HDO doesn't generate gas, as a by-product.

**Figure 17** Effect of preparation method for bimetallic carbide catalysts on (a) conversion and diesel yield, (b) gas product composition, (c) contribution of HDO and DCO<sub>x</sub> were performed at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

The functional group of liquid products catalyzed by CoMoC/Al, CoMoC/Al-TPR, NiMoC/Al, NiMoN/Al-TPR catalysts and PFAD feedstock were characterized by Fourier transform infrared (FTIR) spectroscopy are shown in Figure 18. Triglyceride and free fatty acids peak cannot be observed in green diesel spectrums of bimetallic carbide catalysts, confirming that the bimetallic carbide catalysts prepared by the single-step decomposition and TPR methods completely converted to green diesel products.

**Figure 18** The FT-IR spectrums of liquid products catalyzed by (a) PFAD, (b) CoMoC/Al, (c) CoMoC/Al-TPR, (d) NiMoC/Al and (e) NiMoN/Al-TPR catalysts.

## 5.2 Optimal operating parameter

In this section, the effect of operating temperature and hydrogen pressure on the conversion, selectivity, yield, gas product composition and contribution of HDO and DCO<sub>x</sub> were investigated. The temperature was investigated in the range of 300 °C to 390 °C and hydrogen pressure was studied at 3 MPa and 5 MPa with fixed the other conditions: 1 h<sup>-1</sup> of LSHV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/Feed ratio. The CoMoC/Al and CoMoN/Al catalysts were selected to study effect of temperature and pressure on the activity of the catalysts.

**Table 19** Effects of temperature and hydrogen pressure on conversion, selectivity, yield, product phase and product color.

Catalysts	Parameter	T. (°C)	P. (MPa)	Conversion (%)	Selectivity (%)			Yield (%)		Product phase	Product color
					Diesel selectivity (%)	Gasoline selectivity (%)	Diesel yield (%)	Gasoline yield (%)			
CoMoC/Al	Temp.	300	5	84	99.5	0.5	75.6	0.4	Liquid	Yellow	
		330	5	98	99.3	0.7	84.8	0.6	Liquid	Clear	
		360	5	99	98.2	1.8	75.7	1.3	Liquid	Light green	
		390	5	99	97.2	2.8	73.7	2.1	Liquid	Light green	
CoMoN/Al	Temp.	300	5	54	97.8	2.2	39.4	0.9	Solid+	Light brown	
		330	5	94	98.8	1.2	67.1	0.8	Liquid	Yellow	
CoMoN/Al	Temp.	360	5	97	98.3	1.7	69.6	1.2	Liquid	Clear	
		390	5	96	97.2	2.8	69.8	2.0	Liquid	Light green	
CoMoN/Al	Pressure	330	3	96	99.3	0.7	82.9	0.6	Liquid	Clear	
		330	5	98	99.3	0.7	84.8	0.6	Liquid	Clear	
CoMoN/Al	Pressure	330	3	91	98.8	1.2	64.7	0.8	Liquid	Yellow	
		330	5	94	98.8	1.2	67.1	0.8	Liquid	Yellow	

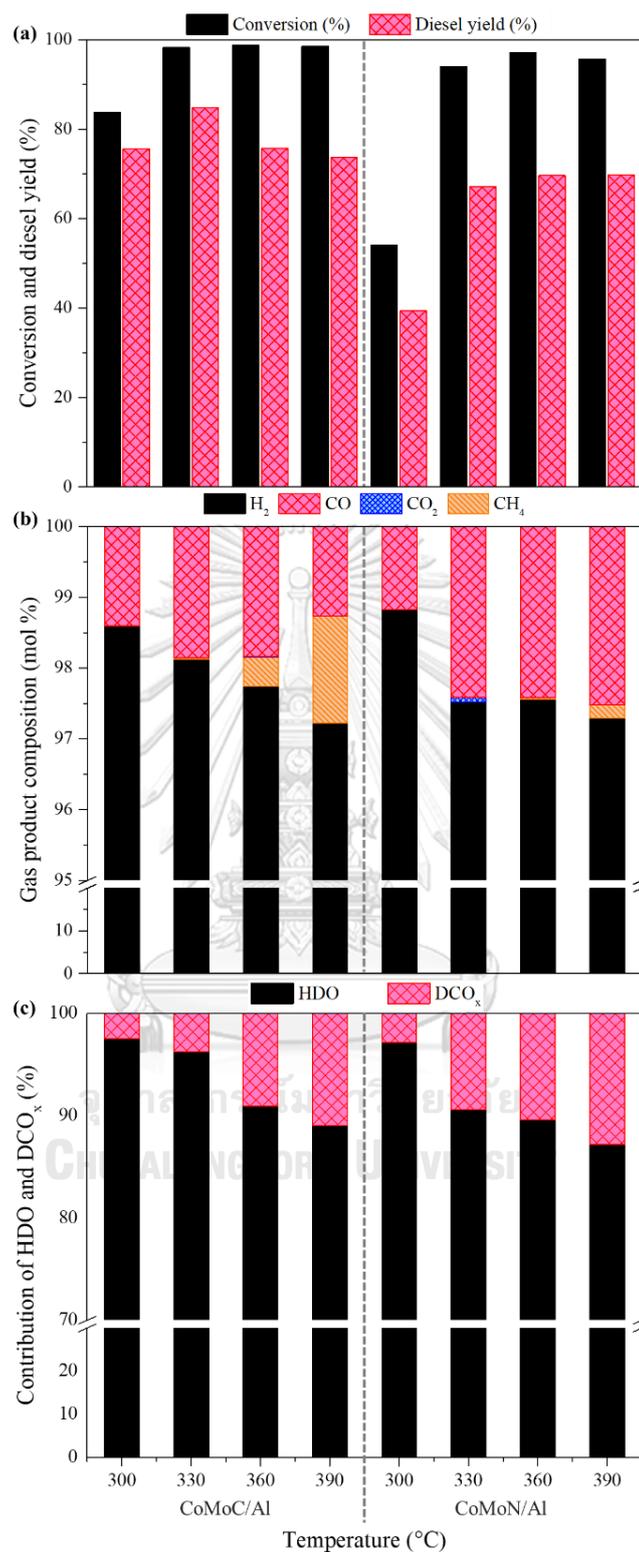

### 5.2.1 Effect of temperature

The effect of the temperature on the hydrotreating process was carried out using CoMoC/Al and CoMoN/Al catalysts in a continuous process. The temperature was studied in the range of 300 °C to 390 °C under fixed 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LSHV, and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

PFAD conversion and diesel yield of CoMoC/Al and CoMoN/Al catalysts are shown in Figure 19a. The optimal temperature of the deoxygenation reaction in a continuous process was 330 °C, which highest PFAD conversion and diesel yield of CoMoC/Al catalyst were 98% and 84.8%, respectively. While conversion and diesel yield of the temperature at 300 °C decreased to 84% and 75.6%, respectively because of the low activity of catalyst in low reaction temperature. At a temperature of 330 °C, PFAD conversion and diesel yield of CoMoN/Al catalyst were 94% and 67.1%, respectively. While the conversion and diesel yield of CoMoN/Al catalyst from temperature of 300 °C were 54% and 39.4%, respectively, which was solid phase at room temperature (See Table 17). When the temperature increased from 360 °C to 390 °C, conversions remained constant while diesel yield decreased because the higher temperature increasing the gasoline yield.

Gas product composition of CoMoC/Al and CoMoN/Al catalysts are shown in Figure 19b. High CH<sub>4</sub> gas composition in the hydrotreating temperature of 360 °C and 390 °C of CoMoC/Al due to the increase in cracking, isomerization, and cyclization reaction when the temperature is higher [70].

Liquid product composition and contribution of HDO and DCO<sub>x</sub> are shown in Figure 19c. The increases in temperature, %DCO<sub>x</sub> slightly increased the contribution of HDO and DCO<sub>x</sub> for both catalysts (CoMoC/Al and CoMoN/Al). These results were consistent to previous studies as increase in temperature increased %DCO<sub>x</sub> contribution [50], resulting from the endothermic DCO<sub>x</sub> pathway. Therefore, the increased contribution of DCO<sub>x</sub>, increasing the sum of CO, CO<sub>2</sub> and CH<sub>4</sub> in gas product composition (See Figure 19b).

**Figure 19** Effect of temperature of CoMoC/Al and CoMoN/Al catalysts on (a) conversion and diesel yield (b) gas product composition (c) contribution of HDO and DCO<sub>x</sub> were performed at 5MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

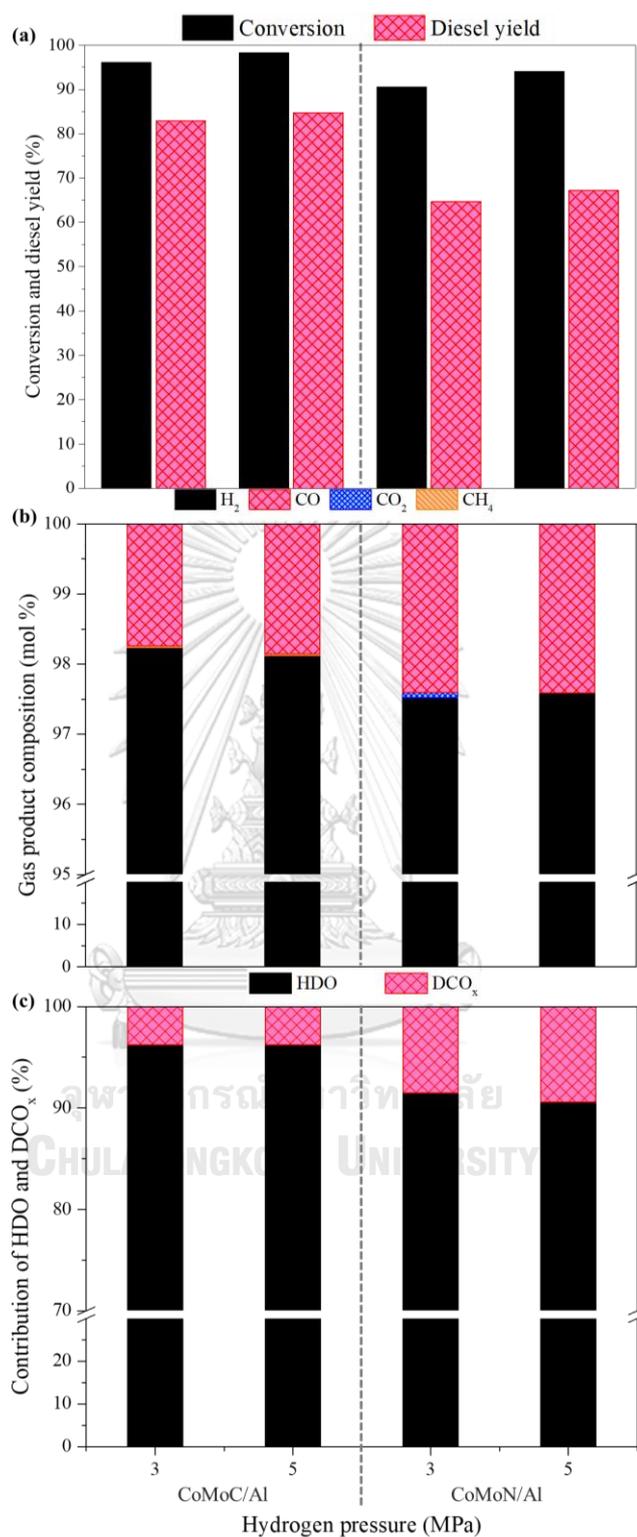

### 5.2.2 Effect of hydrogen pressure

The effect of the hydrogen pressure on the hydrotreating process was carried out over CoMoC/Al and CoMoN/Al catalysts in a continuous process. The pressure was studied at 3 MPa and 5 MPa under fixed 330 °C of temperature, 1 h<sup>-1</sup> of LSHV, and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

The effect of hydrogen pressure of CoMoC/Al and CoMoN/Al catalysts on conversion and diesel yield are shown in Figure 20a. The conversion, selectivity, yield, product phase and product color exhibits are summarized in Table 17. Conversion and diesel yield of CoMoC/Al and CoMoN/Al catalysts gradually decreased when decreasing hydrogen pressure from 5 MPa to 3 MPa. The CoMoC/Al catalyst showed higher diesel yield than CoMoN/Al catalyst at 3 MPa of hydrogen pressure, which diesel yield of CoMoC/Al and CoMoN/Al catalyst was 82.9% and 64.7%, respectively. At 5 MPa of hydrogen pressure, diesel yield of CoMoC/Al catalyst (84.8%) higher than CoMoN/Al catalyst (67.1%). This result indicates that the decrease of the pressure from 5 MPa to 3 MPa had a small effect on the catalyst activity.

The Effect of hydrogen pressure of CoMoC/Al and CoMoN/Al catalysts on gas product composition are shown in Figure 20b. Gas product compositions (Mixed of CO, CO<sub>2</sub> and CH<sub>4</sub> gas) of CoMoC/Al catalyst were approximate 1.8 mol%-1.9 mol%. Likewise, Gas product compositions (Mixed of CO, CO<sub>2</sub> and CH<sub>4</sub> gas) of CoMoN/Al catalyst were approximate 2.4 mol%-2.5 mol%. Besides, CO<sub>2</sub> gas at 3 MPa of hydrogen pressures is observed. As a result of the decreased hydrogen pressures from 5 MPa to 3 MPa with decreasing methanation (Side reaction of deoxygenation). Thus, CO<sub>2</sub> doesn't convert to CH<sub>4</sub> by methanation.

The Effect of hydrogen pressure of CoMoC/Al and CoMoN/Al catalysts on the contribution of HDO and DCO<sub>x</sub> are shown in Figure 20c. Decreasing hydrogen pressure had not significant effect on the reaction pathway of deoxygenation at a temperature of 330 °C.

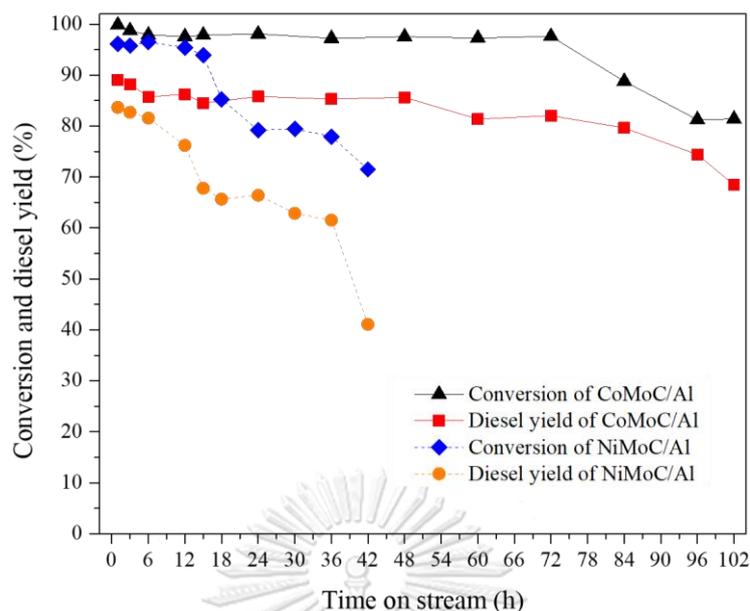

**Figure 20** Effect of hydrogen pressure of CoMoC/Al and CoMoN/Al catalysts on (a) conversion and diesel yield (b) gas product composition (c) contribution of HDO and DCO<sub>x</sub> were performed at 330 °C of temperature, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

### 5.3 Stability of catalysts

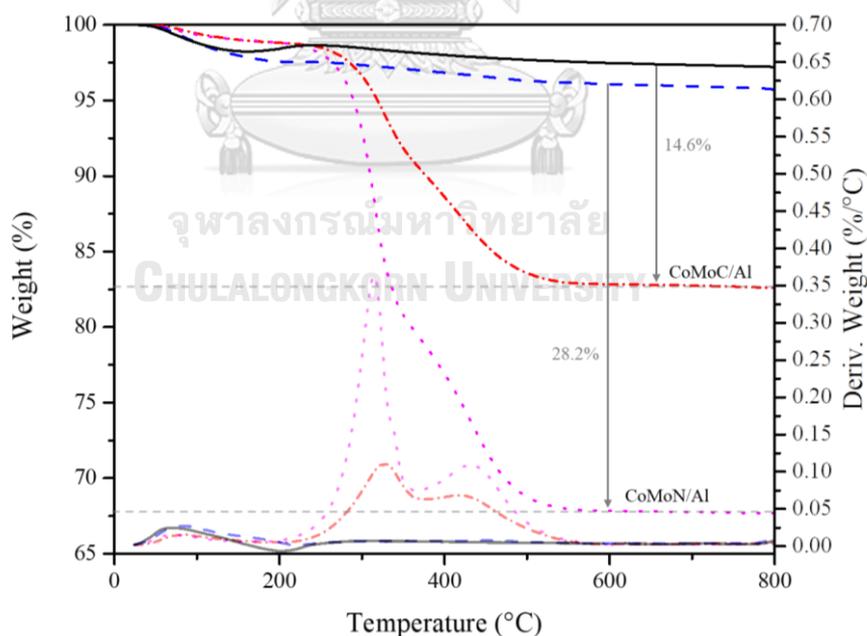

From the result of catalysis screening and optimal operating conditions, CoMoC/Al and CoMoN/Al catalysts show high activity than other catalysts. The operating conditions at 330 °C of temperature and 5 MPa of hydrogen pressure were optimal operating parameter for catalytic deoxygenation. Therefore, in the section, the stability of CoMoC/Al and CoMoN/Al catalysts in deoxygenation of PFAD were studied in a trickle bed reactor at 330 °C of temperature, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio. The stability of CoMoC/Al and CoMoN/Al catalysts on PFAD conversion and diesel yield are shown in Figure 21. The PFAD conversion of CoMoC/Al catalyst remained constant to 72 h. and then decreased meanwhile, the PFAD conversion of CoMoN/Al catalyst remained constant to 18 h. and then decreased. In addition, the diesel yield of CoMoC/Al catalyst remained constant to 72 h. and then decreased slowly, but the diesel yield of CoMoN/Al catalyst significantly dropper after 6 h.

The TGA profiles of spent catalysts after the catalytic stability test are exhibited in Figure 22. The different weight loss between fresh and spent of CoMoC/Al and CoMoN/Al catalysts were 14.6% and 28.2%, respectively. Although the long-term reaction tests of CoMoC/Al catalysts were performed for 102 h. on-stream, the CoMoC/Al catalyst showed low weight loss, indicating high stability and low deactivation of CoMoC/Al catalyst in compared with CoMoN/Al catalyst.

**Figure 21** Catalytic stability test of CoMoC/Al and NiMoC/Al catalysts on conversion and diesel yield effect were performed at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

**Figure 22** TG/DTG profiles of the fresh and spent catalysts on catalytic stability test. The operating condition at a temperature of 330 °C, 5 MPa of hydrogen pressure, 1 h<sup>-1</sup> of LHSV and 1000 N(cm<sup>3</sup>·cm<sup>-3</sup>) of H<sub>2</sub>/feed ratio.

## CHAPTER VI

### CONCLUSION

This work aims to produce green diesel from PFAD (palm fatty acid distillate, a residual from palm oil refinery) using transition metal and non-sulfide catalysts via deoxygenation in a trickle bed reactor. The Mo nitride-based catalysts were prepared by the single-step decomposition method, while the Mo carbide-based catalysts were prepared by the single-step decomposition and the temperature-programmed reduction method. The properties of catalysts were investigated by XRD, XPS, SEM/EDX, N<sub>2</sub>-physisorption and TGA. The catalytic performance was evaluated considering PFAD conversion, diesel yield and contribution of HDO and DCO<sub>x</sub>.

The catalyst performance was evaluated at a temperature of 330 °C, hydrogen pressure of 5 MPa, LHSV of 1 h<sup>-1</sup>, and H<sub>2</sub>/feed ratio of 1000 Ncm<sup>3</sup>·cm<sup>-3</sup>. It was found that the carbide catalysts exhibited the superior performance than those of nitride catalysts. The bimetallic CoMoC showed higher diesel yield than monometallic Mo carbide and bimetallic NiMoC catalysts. Thus, the CoMoC and NiMoC catalysts were selected for further investigations. The hydrodeoxygenation (HDO) is a dominant reaction pathway for all catalysts.

The catalysts prepared by a single-step decomposition method exhibited higher catalytic activity than that of the catalysts prepared by temperature-programmed reduction method due to higher catalyst surface area. Consequently, the single-step composition method is a good alternative for the preparation of a bimetallic carbide catalyst.

In order to optimize the operating conditions, the operating temperatures were varied from 300 to 390 °C under 3-5 MPa of hydrogen pressure. The operating temperature of 330 °C and 5 MPa of hydrogen pressure was found to be a suitable condition for CoMoC and NiMoC catalysts. The reaction temperature and hydrogen pressure have slight effects on reaction pathways.

In the stability test, the CoMoC catalyst exhibited complete PFAD conversion with a diesel yield of 82.0% for 72 h. time on stream. However, the catalytic activity of CoMoC catalyst gradually decreased after 72 h., and PFAD conversion of 81% with diesel yield of 68.5% were obtained after 102 h. time on stream.

**APPENDIX C**  
**CONDITION OF GAS CHROMATOGRAPY AND**  
**CALIBRATION CURVES OF STANDARDS**

**Table C.1** Components of n-C<sub>5</sub> to n-C<sub>44</sub> alkanes in calibration mixture. (Songphon 2011).

<b>Elution order</b>	<b>Compound</b>	<b>CAS#</b>	<b>Percent Purity</b>	<b>Concentration (wt.%)</b>
1	n-Pentane (C <sub>5</sub> )	109-66-0	99%	0.9995 wt./wt.%
2	n-Hexane (C <sub>6</sub> )	110-54-3	99%	0.9995 wt./wt.%
3	n-Heptane (C <sub>7</sub> )	142-82-5	99%	0.9995 wt./wt.%
4	n-Octane (C <sub>8</sub> )	111-65-9	99%	0.9995 wt./wt.%
5	n-Nonane (C <sub>9</sub> )	111-84-2	99%	0.9995 wt./wt.%
6	n-Decane (C <sub>10</sub> )	124-18-5	99%	0.9995 wt./wt.%
7	n-Undecane (C <sub>11</sub> )	1120-21-4	99%	0.9995 wt./wt.%
8	n-Dodecane (C <sub>12</sub> )	112-40-3	99%	0.9995 wt./wt.%
9	n-Tetradecane (C <sub>14</sub> )	629-59-4	99%	0.9995 wt./wt.%
10	n-Pentadecane (C <sub>15</sub> )	629-62-9	99%	0.9995 wt./wt.%
11	n-Hexadecane (C <sub>16</sub> )	544-76-3	99%	0.9995 wt./wt.%
12	n-Heptadecane (C <sub>17</sub> )	629-78-7	99%	0.9995 wt./wt.%
13	n-Octadecane (C <sub>18</sub> )	593-45-3	99%	0.9995 wt./wt.%
14	n-Eicosane (C <sub>20</sub> )	112-95-8	99%	0.9995 wt./wt.%
15	n-Tetracosane (C <sub>24</sub> )	646-31-1	99%	0.9995 wt./wt.%
16	n-Octacosane (C <sub>28</sub> )	630-02-4	99%	0.9995 wt./wt.%
17	n-Dotriacontane (C <sub>32</sub> )	544-85-4	98%	0.9991 wt./wt.%
18	n-Hexatriacontane (C <sub>36</sub> )	630-06-8	99%	0.9995 wt./wt.%
19	n-Tetracontane (C <sub>40</sub> )	4181-95-7	97%	0.9986 wt./wt.%
20	n-Tetracontane (C <sub>44</sub> )	7098-22-8	99%	0.9995 wt./wt.%
Solvent	Carbon Disulfide	75-15-0	99%	

**Table C.2** Condition of GC-FID for calibration curve.

<b>Condition</b>	<b>Value</b>
Air (kPa)	50
H <sub>2</sub> (kPa)	80
Carrier (kPa)	40
Make up (kPa)	40
Split (ml min <sup>-1</sup> )	30
Purge (ml min <sup>-1</sup> )	4

**Table C.3** Retention time for each hydrocarbon component in calibration mixture.

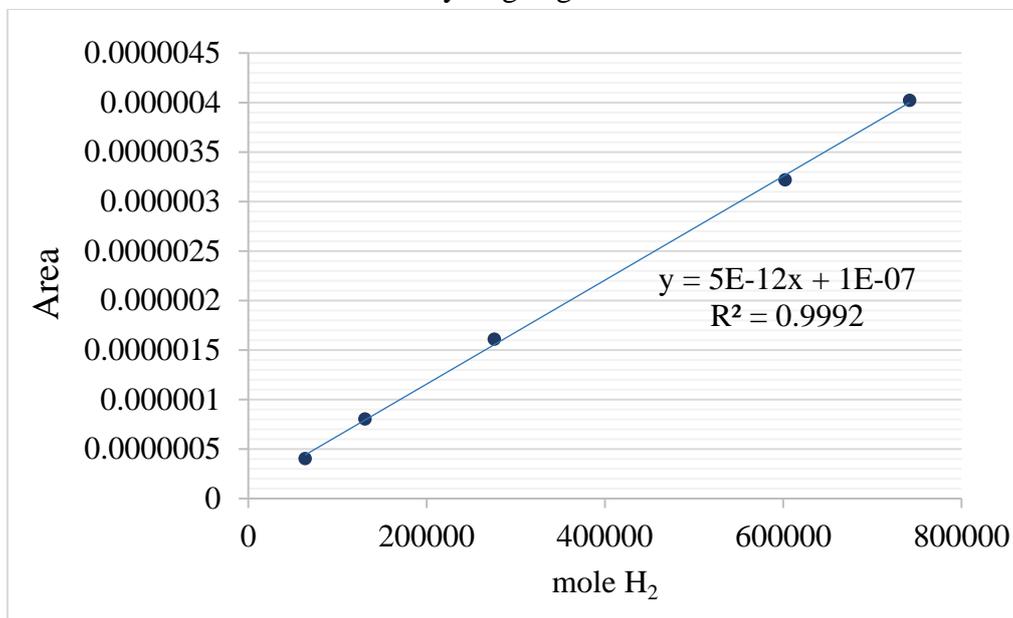

<b>Components</b>	<b>Retention time (Average)</b>
n-Pentane (C5)	0.25
n-Hexane (C6)	0.45
n-Heptane (C7)	0.87
n-Octane (C8)	1.58
n-Nonane (C9)	2.53
n-Decane (C10)	3.6
n-Undecane (C11)	4.69
n-Dodecane (C12)	5.74
n-Tetradecane (C14)	7.71
n-Pentadecane (C15)	8.61
n-Hexadecane (C16)	9.45
n-Heptadecane (C17)	10.26
n-Octadecane (C18)	11.02
n-Eicosane (C20)	12.43
n-Tetracosane (C24)	14.88
n-Octacosane (C28)	16.96
n-Dotriacontane (C32)	18.76
n-Hexatriacontane (C36)	20.32
n-Tetracontane (C40)	21.98

**Table C.4** Density and molecular weight for component in calibration mixture.  
(Songphon 2011)

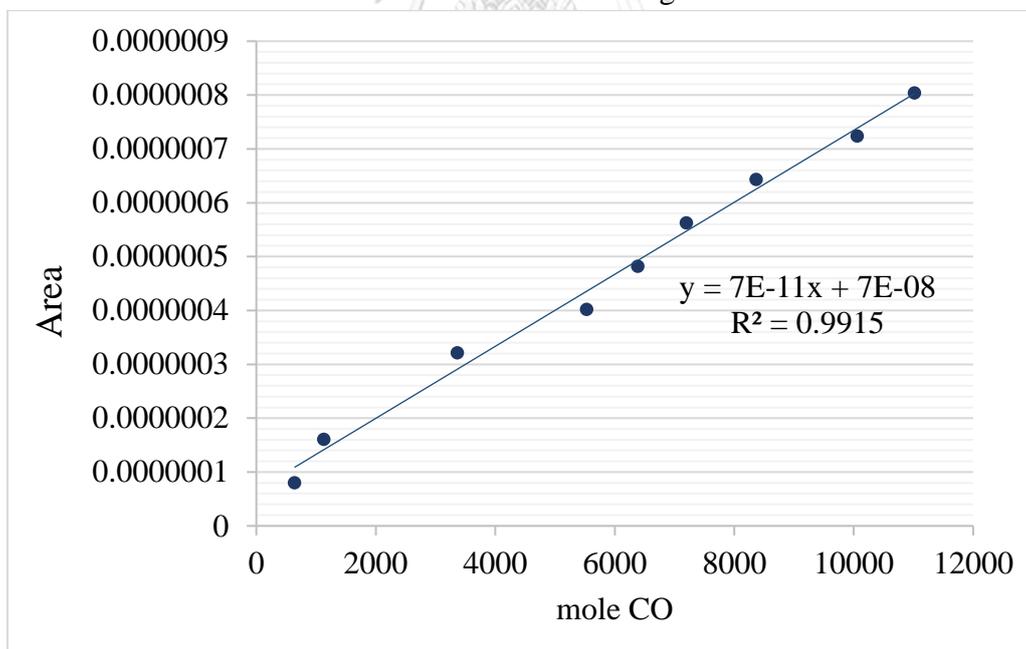

<b>Component</b>	<b>Density (g/cm<sup>3</sup>)</b>	<b>Molecular weight (g/mol)</b>
n-Pentane (C5)	0.626	72.15
n-Hexane (C6)	0.659	86.18
n-Heptane (C7)	0.684	100.20
n-Octane (C8)	0.703	114.23
n-Nonane (C9)	0.718	128.26
n-Decane (C10)	0.730	142.28
n-Undecane (C11)	0.740	156.31
n-Dodecane (C12)	0.749	170.33
n-Tetradecane (C14)	0.763	198.39
n-Pentadecane (C15)	0.769	212.42
n-Hexadecane (C16)	0.773	226.44
n-Heptadecane (C17)	0.777	240.47
n-Octadecane (C18)	0.777	254.5
n-Eicosane (C20)	0.789	282.55
n-Tetracosane (C24)	0.797	338.66
n-Octacosane (C28)	0.8067	394.76
n-Dotriacontane (C32)	0.812	450.87
n-Hexatriacontane (C36)	0.7795	506.97
n-Tetracontane (C40)	0.7785	563.08
n-Tetracontane (C44)	0.82	
Carbon Disulfide	1.261	76.139

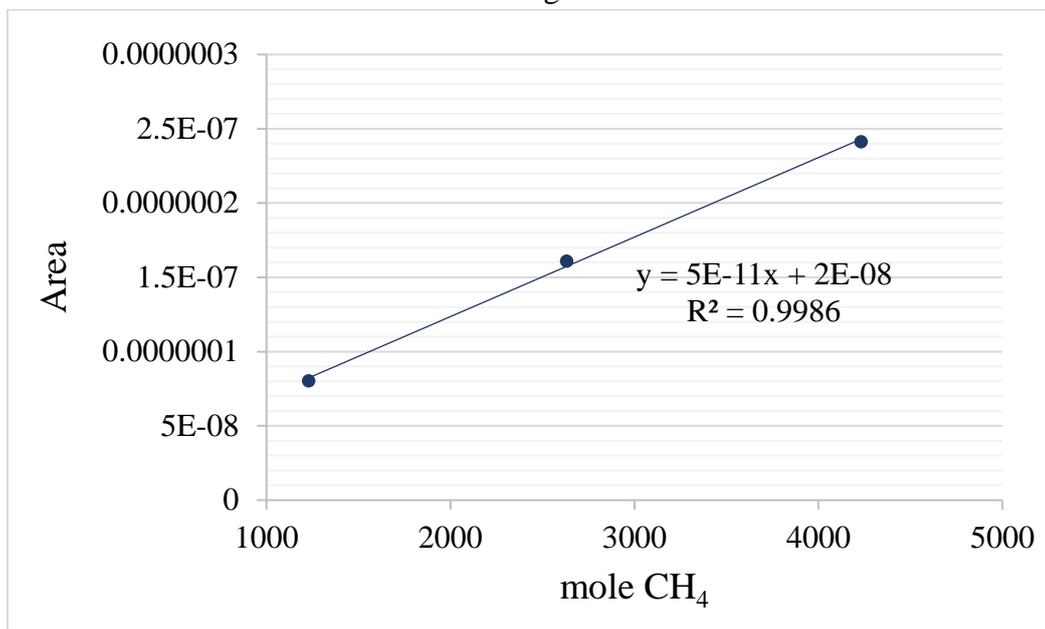

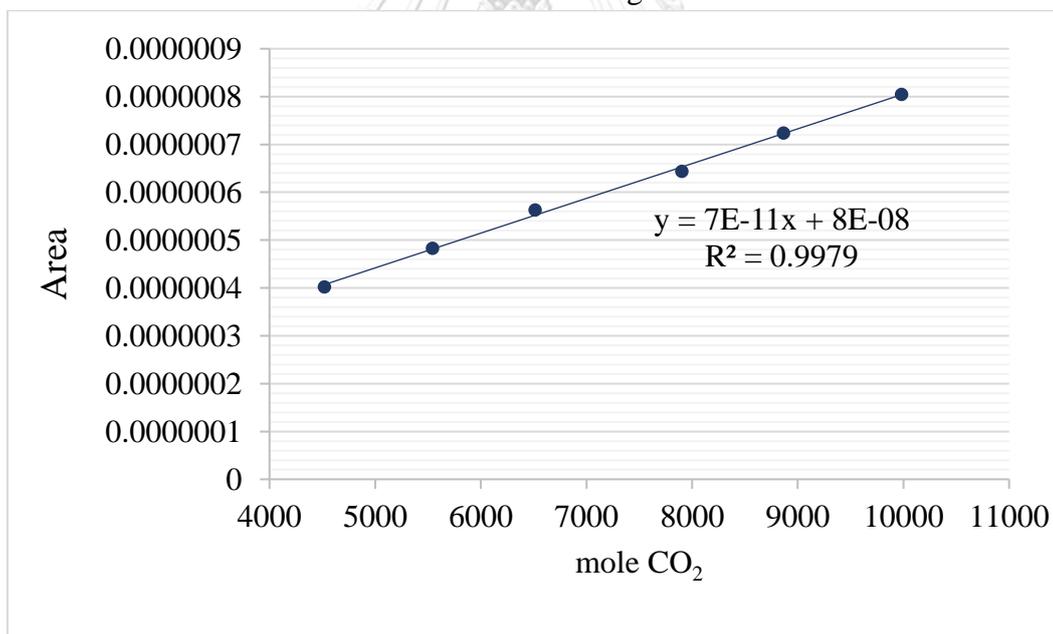

### Calibration curve for gaseous product

**Table C.5** Calibration curve for hydrogen gas.
