KEYWORD Cyclodextrin Radiopharmaceuticals Gallium-68 Radiochemical  
D: purity

Sirapop Sriaumpai : RADIOSYNTHESIS OF NOVEL <sup>68</sup>Ga-LABELLED- $\alpha$ -CYCLODEXTRIN FOR PET IMAGING. Advisor: Assoc. Prof. PHATSAWEE JANSOOK, Ph.D. Co-advisor: Assoc. Prof. SHUICHI SHIRATORI, Ph.D.

Cyclodextrins (CDs) are cyclic oligosaccharides composed of glucose units linked by  $\alpha$ -1,4 glycosidic bond. CDs are commonly used as pharmaceutical excipients and they offer versatile benefits in various industries. Recently, CDs have been promising for the application of medical imaging, especially nuclear medicine imaging. Herein, we aim to radiosynthesize <sup>68</sup>Ga- $\alpha$ -cyclodextrin (<sup>68</sup>Ga- $\alpha$ CD) by directly radiolabeling Ga-68 to  $\alpha$ CD. Briefly, Ga-68 was eluted, mixed with  $\alpha$ CD solution and heated at 100 °C for 20 min. Subsequently, the reaction was allowed to cool down at room temperature. The resulting <sup>68</sup>Ga- $\alpha$ CD was characterized using mass spectrometry (MS) and elucidated by in silico computational studies. Radioactivity was measured using instant thin layer chromatography. The radiochemical purity (RCP) was calculated. The pH of the resulting solution was measured using a pH meter. The radiosynthesis process was then optimized and purified to increase the RCP of <sup>68</sup>Ga- $\alpha$ CD. The radiostabilizers, i.e., sodium ascorbate or ascorbic acid, were selected, various concentrations of  $\alpha$ CD solutions (0.25–5 mg/ml) and  $\alpha$ CD polymer were included to optimize the process and C-18 cartridge was employed to purify <sup>68</sup>Ga- $\alpha$ CD solution. Initially, the RCP of <sup>68</sup>Ga- $\alpha$ CD is very low ( $0.24 \pm 0.03\%$ ). Upon the optimization using sodium ascorbate as radiostabilizer together with 1 mg/ml  $\alpha$ CD solution and further purification using C-18 cartridge, the RCP is significantly increased. Ultimately, we have successfully achieved an RCP of  $18.4 \pm 1.1\%$ . Subsequently, miconazole or cyclosporin A was introduced into the  $\alpha$ CD cavity prior to radiolabeling, but no significant impact on the binding affinity between Ga-68 and  $\alpha$ CD was observed. This is subsequently confirmed by MS and computational studies that the stoichiometry ratio of Ga-68 and  $\alpha$ CD is 1:1 complex and binding site of Ga-68 is on either primary or secondary rim of  $\alpha$ CD.

## ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to my advisor, Assoc. Prof. Phatsawee Jansook, Ph.D. and my co-advisor, Assoc. Prof. Shuichi Shiratori, Ph.D., for their invaluable guidance, encouragement, kindness, and unwavering support throughout the course of this research. Without their mentorship, my thesis would not have reached its accomplishment.

Heartfelt thanks extend to my thesis committee for insightful suggestions and comments, enabling me to improve my thesis.

I am indebted to the Queen Sirikit Centre for Breast Cancer for providing me with a scholarship for pursuing my master's degree.

My incredibly grateful to Dr. Patanachai Limpikirati from the Department of Food and Pharmaceutical Chemistry, Faculty of Pharmaceutical Sciences Chulalongkorn University, and Mr. Thanundorn Thanusuwanasak from the Pharmaceutical Research Instrument Center, Faculty of Pharmaceutical Sciences Chulalongkorn University for their unwavering and generous support in mass spectrometry study.

My sincere thanks to Assoc. Prof. Thanyada Rungrotmongkol, Ph.D. and Mr. Aamir Aman from the Department of Biochemistry, Faculty of Sciences, Chulalongkorn University for their generous support in computational study.

A special appreciation goes to the Master of Sciences program in Pharmaceutical Sciences and Technology for granting me admission to the program.

A special acknowledgement goes to the Division of Nuclear Medicine, Department Radiology, Faculty of Medicine, Siriraj Hospital, Mahidol University including the staffs for granting me access to their hot lab, which was indispensable for the completion of this research. Additionally, I would like to thank all staff in the Department of Pharmaceutics and Industrial Pharmacy, Faculty of Pharmaceutical Sciences, Chulalongkorn University for their laboratory equipment support.

Finally, I would like to thank all my lab members especially Dr. Hay Man Saung Hnin Soe, Ms. Phyto Darli Myo Maw, Ms. Hay Marn Hnin and Ms. Theingi Tun for their kindness and helpfulness throughout my academic journey.

## Chapter I

### Introduction

Cyclodextrins (CDs) are cyclic oligosaccharides consisting of glucopyranose units linked by  $\alpha$ -1,4 glycosidic bonds. They possess cone-shaped structures capable of forming inclusion complexes, resulting in enhanced aqueous solubility of poorly water-soluble drugs. The natural CDs are  $\alpha$ -cyclodextrin ( $\alpha$ CD),  $\beta$ -cyclodextrin ( $\beta$ CD) and  $\gamma$ -cyclodextrin ( $\gamma$ CD), which are composed of 6, 7, or 8 glucose units, respectively (1). The natural CDs and their guest/CD complexes have limited aqueous solubility. Various CD derivatives, such as hydroxypropyl and randomly methylated CDs, have been introduced to improve their solubility and that of their complexes (2). CDs are enabled excipients in pharmaceutical products, and they offer versatile benefits in many industries, such as food, textiles and packaging, cosmetics and personal care, and the separation process. Recently, CDs have been interesting for the application of medical imaging, especially in the field of nuclear medicine (3).

Nuclear medicine is a specialty within radiology, employs radiopharmaceuticals for diagnostic, therapeutic or theranostic purposes. While the primary route of administration for radiopharmaceuticals is intravenous, alternative routes such as ingestion or inhalation can be employed for specific agents (4). In the diagnostic approach, nuclear medicine employs advanced imaging modality such as single photon emission computed tomography (SPECT) and positron emission tomography (PET) to detect the distribution and accumulation of radiopharmaceuticals within organ or tissue of patient's body (5). In the therapeutic approach, nuclear medicine utilizes high linear energy transfer (LET) radiopharmaceuticals to inflict damage on targeted cells or tissue. Its principle lies in cancer treatment, encompassing both curative and palliative treatment (6, 7). Moreover, it exhibits efficacy in treating micro-metastasis that cannot be detected by conventional imaging technique (8). In theranostic approach, it is considered as precision medicine. This approach is a combination of diagnostic and therapeutic approaches. It employs two radiopharmaceuticals sharing the same ligand but featuring different radionuclide. It is primarily used in oncology applications. Low

LET radionuclides such as Gallium-68 (Ga-68) are employed for pinpointing tumor site, meanwhile high LET radionuclides, for example, Lutetium-177 (Lu-177) are harnessed for neutralizing the tumor (8, 9).

Among all PET radionuclides, Ga-68 stands out as one of the most frequently employed radionuclides because it can be easily obtained from  $^{68}\text{Ge}/^{68}\text{Ga}$  generator (10). Its primary utilization lies in theranostic approach, often in conjunction with Lu-177 as previously mentioned above. However, the scope of its application extends beyond clinical use. Researchers have found its potential to be used in tracking specific molecules of interest by radiolabeling with Ga-68, enabling the observation of their biodistribution.

Hajdu et al. (2019) (11) studied the *in vivo* distribution of 2-hydroxypropyl- $\beta$ -cyclodextrin (HP $\beta$ CD) in normal mice by radiolabeling with  $^{68}\text{Ga}$ -1,4,7-triazacyclononane,1-glutaric acid-4,7-acetic acid (NODAGA).  $^{68}\text{Ga}$ -NODAGA-HP $\beta$ CD has high radiochemical purity, stability, favorable pharmacokinetics in a mouse model and partition coefficient (log P value) at -3.07. One year later, the same research group investigated the biodistribution of the prostaglandin E2 (PGE2)/randomly methylated  $\beta$ -cyclodextrin (RM $\beta$ CD) complex in normal mice and PGE2 positive tumor-bearing mice by radiolabeling with  $^{68}\text{Ga}$ -NODAGA (12). The log P value of  $^{68}\text{Ga}$ -NODAGA-RM $\beta$ CD is -3.63. A high standard uptake value (SUV) and accumulation of  $^{68}\text{Ga}$ -NODAGA-RM $\beta$ CD at the tumor site were observed in the tumor-bearing mice group. In mid-2022, Csige et al. (2022) (13) investigated the *in vivo* distribution of RM $\beta$ CD in normal mice and tumor-bearing mice by radiolabeling with  $^{68}\text{Ga}$ - 1,4,7,10-tetraazacyclododececane,1-(glutaric acid)-4,7,10-triacetic acid (DOTAGA), and  $^{205/206}\text{Bi}$ -DOTAGA. The log P value of  $^{68}\text{Ga}$ -DOTAGA-RM $\beta$ CD and  $^{205/206}\text{Bi}$ -DOTAGA are -3.47 and -3.45 respectively. Again, in the tumor-bearing mice, high SUV and accumulation of  $^{68}\text{Ga}$ -DOTAGA-RM $\beta$ CD at the tumor site were also detected. In late 2022, Szabo et al. (2022) (14) evaluated the *in vivo* PET imaging of  $^{68}\text{Ga}$ -NODAGA- RM $\beta$ CD and  $^{68}\text{Ga}$ -NODAGA-HP $\beta$ CD compared with  $^{18}\text{F}$ -Fluorodeoxyglucose ( $^{18}\text{F}$ -FDG) in a tumor model.  $^{68}\text{Ga}$ -NODAGA-RM $\beta$ CD and  $^{68}\text{Ga}$ -NODAGA-HP $\beta$ CD uptake at the tumor site. However, the accumulation and SUV of both radiopharmaceuticals were lower than those of  $^{18}\text{F}$ -FDG.

As aforementioned above, CD-based radiopharmaceuticals have the potential for PET imaging and can be further developed and expanded for other applications in nuclear medicine. For example, tracking the biodistribution of drugs in a formulation containing CD as an excipient, the synergistic or additive effects of chemotherapy drug/CD complexes, and radiolabeled with  $\beta$ - or  $\alpha$ -emitting radionuclide for tumor killing. Based on our best knowledge, there are no reports regarding direct radiolabeling between CDs and radionuclides. Thus, in this study, we performed and optimized a radiosynthesis of  $\alpha$ CD labeled with Ga-68 ( $^{68}\text{Ga-}\alpha\text{CD}$ ) by directly labelling.  $\alpha$ CD was selected due to its high aqueous solubility and applicable use in parenteral preparations.  $^{68}\text{Ga-}\alpha\text{CD}$  was characterized in terms of the radiochemical purity (RCP) using thin layer chromatography (TLC). Mass spectrometry (MS), and the pH of solutions were also measured. The *in silico* computational study was carried out to identify the binding site of Ga-68 on  $\alpha$ CD. Subsequently, the effect of radiostabilizers, the concentrations of ligand (i.e.,  $\alpha$ CD) were determined and the purification step using C-18 cartridge was performed for the optimization process. Finally, the effect of the drug binding capacity to  $\alpha$ CD, the model drugs (i.e., miconazole and cyclosporin A) were incorporated in  $^{68}\text{Ga-}\alpha\text{CD}$  solutions and the resulting RCP in the presence and absence drugs was compared. Therefore, the main objectives of this study are as follow:

- To develop and optimize a novel  $\alpha$ CD directly labeled with Ga-68.
- To determine the drug binding capacity of neat  $\alpha$ CD and  $^{68}\text{Ga-}\alpha\text{CD}$ .

## Chapter II

### Literature review

#### 2.1 Cyclodextrins

CDs are macrocyclic glucopyranose units composed of glucose units connected by  $\alpha$ -1,4 glycosidic bond (1-3, 15, 16). CDs are produced from starch by the enzyme CD glucosyltransferase (CGTase). CDs are commonly used as pharmaceutical excipients due to their ability to form an inclusion complex with various guest molecules, mainly via van der Waals force. CDs are doughnut-shaped molecules with hydrophilic exterior and a somewhat lipophilic central cavity. In aqueous solutions CDs are able to form water-soluble inclusion complexes of lipophilic poorly soluble drugs by encapsulating some lipophilic moiety of the drugs into the central cavity (1) (Figure 1). The natural CDs,  $\alpha$ CD,  $\beta$ CD and  $\gamma$ CD correspond to 6, 7, and 8 glucopyranose units, respectively (Figure 2). All 3 natural forms are considered as safe by FDA (15). The CGTases are produced by a variety of bacteria, mainly *Bacillus* species (3, 16). Among the natural CDs,  $\beta$ CD has the lowest aqueous solubility due to its rigid structure. Meanwhile, the longer chain more flexible structure of  $\gamma$ CD exhibits the highest aqueous solubility (16).

**Figure 1.** Formation of an inclusion complex in aqueous solution.

$K_{1:1}$  is the equilibrium constant (i.e. the stability constant) where 1:1 indicates the stoichiometry of the complex (1).

**Figure 2.** The structures of (A)  $\alpha$ CD, (B)  $\beta$ CD, and (C)  $\gamma$ CD. Adapt from (17)

To improve the solubility of natural CDs, the structure of natural CDs must be modified. Substitution of existing hydroxy group with hydroxypropyl, methyl or sulfobutylether proves to be an effective way to improve not just solubility but also physiochemical and biological properties (2). There are three hydroxy groups on CD that can be modified. The first one is a hydroxy group at position 6 on the primary face or narrow rim of the molecule; it is the most basic and nucleophilic (Figure 3). The second hydroxy group is a hydroxy group in 2-position located on the secondary face or wide rim of the molecule; it is the most acidic group. The final hydroxy group is at 3-position, which is also located on the secondary face; it is the most inaccessible group (16, 18, 19). Table 1 shows the physiochemical properties of natural CDs and their derivatives.

**Figure 3.** 3D structure of cyclodextrins. Adapt from (19)

**Table 1.** physiochemical properties of natural CDs and their derivatives (*Modified from (16).*)

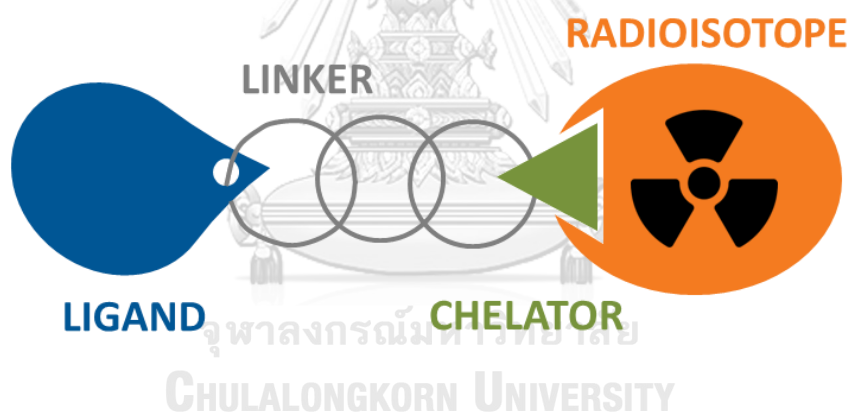

Cyclodextrin	Number of substituents <sup>a</sup>	Molecular weight (g/mol)	Solubility in water (mg/ml) <sup>b</sup>
$\alpha$ -Cyclodextrin ( $\alpha$ CD)	-	972	145
$\beta$ -Cyclodextrin ( $\beta$ CD)	-	1135	18.5
$\gamma$ -Cyclodextrin ( $\gamma$ CD)	-	1297	232

## 2.2 Radiopharmaceuticals

Radiopharmaceuticals are biological radioactive compounds capable of acting as diagnostic and/or therapeutic agents, depending on the type of labeled radionuclides.  $\gamma$  and positron-emitting radionuclides such as Tc-99m and Ga-68 are used in the diagnosis role due to their low LET, whereas  $\alpha$ - and  $\beta$ -emitting radionuclides such as Ac-225 and Y-90 are used in the therapeutic role due to their high LET which capable of inducing DNA strand break (20). However, there are

some radionuclides that are considered as theranostic agents, such as Iodine 131 (I-131), due to the emission of both  $\beta$  particles and  $\gamma$ -rays (20-22). Radiopharmaceuticals usually consist of four parts (Figure 4). The first one is a radionuclide, which emits radiation. The second is a chelator, which binds to radionuclides. The third is the linker, which links the chelator with the ligand; sometimes it can be modified to increase the biological half-life of the compound. The fourth is ligand, which is responsible for binding to the specific receptor on the target organ (21). Radiopharmaceuticals play an important role in several clinical uses like in oncology, cardiology, neurology, and nephrology. Radiopharmaceuticals are also very useful in preclinical study as well. It allows researchers to monitor the cells which are helpful in cell therapy like cancer immunotherapy (23). To detect radiopharmaceuticals, an imaging instrument is needed. Nowadays, the most commonly used instruments are SPECT and PET scans (20-22, 24).

### 2.2.1 Use of radiopharmaceuticals in clinic

In oncology, there are varieties of radiopharmaceuticals that can be employed.  $^{18}\text{F}$ -FDG is commonly employed to detect early-stage and recurrence cancer. It is a glucose analogue which will be highly uptake and accumulate in tumor cells (25).  $^{99\text{m}}\text{Tc}$ -methyl diphosphonate (MDP) can detect bone metastasis due to it typically uptake in area that has high bone turnover or bone formation (26).  $^{177}\text{Lu}$ - prostate-specific membrane antigen (PSMA) emits  $\beta$ - particle that can neutralize prostate cancer cells (22). I-131 is a radioisotope of iodine which is normally uptake by thyroid glands. It emits both  $\gamma$ -ray and  $\beta$  particle, which allowing it to be used for both diagnose and treat thyroid cancer (27). In cardiology,  $^{99\text{m}}\text{Tc}$ -red blood cell (RBC) is used in multigated acquisition (MUGA) scan for evaluate left ventricle ejection fraction.  $^{99\text{m}}\text{Tc}$ -setamibi,  $^{13}\text{N}$ -ammonia,  $^{15}\text{O}$ -water or  $^{82}\text{Rb}$  can be used for myocardial perfusion scan to evaluate coronary artery stenosis (24, 27). In neurology,  $^{99\text{m}}\text{Tc}$ -ethyl cysteinate dimer (ECD) and  $^{99\text{m}}\text{Tc}$ -hexamethylpropyleneamine oxime (HMPAO) are used for brain perfusion scan to evaluate dementia or epilepsy (28, 29).  $^{18}\text{F}$ -fluoro-l-dopa (FDOPA) is used for brain tumor imaging.  $^{18}\text{F}$ -FDG is used for Alzheimer disease diagnosis (24, 27). In nephrology,  $^{99\text{m}}\text{Tc}$ - mercaptoacetyltriglycine (MAG3),  $^{99\text{m}}\text{Tc}$ - diethylene triamine pentaacetic acid (DTPA) and  $^{99\text{m}}\text{Tc}$ - dimercaptosuccinic acid (DMSA) can be used for renal scan (30).

### 2.2.2 Use of radiopharmaceuticals in preclinical research

In preclinical research, radiopharmaceuticals can be used for either *in vivo* molecular tracking or cellular tracking. For molecular tracking, the molecule of interested can be labeled with radionuclide, enabling the determination of molecule distribution (31). For example, Cu-64 has been radiolabeled with DOTA and subsequently bound to camptothecin conjugated with a  $\beta$ CD polymer. This approach enables the tracking of the drug's biodistribution and the acquisition of pharmacokinetic data (3). In case of cellular tracking, stem cells or some immune cells like cytotoxic T cells and dendritic cells can be radiolabeled with radioisotope

either by direct or indirect technique (23). Direct cell labeling method is the most used method due to its simple, safety, and easy to translate into clinical use. The radiopharmaceutical will either bind directly to cell membrane or enter the cell via passive diffusion, uptake by transporter protein, endocytosis, or phagocytosis. However, this method has some minor drawbacks (23, 32). First, the concentration of radiopharmaceuticals will be diluted if the target cells undergo cell division. Secondly, sometimes labeled radiopharmaceuticals can be released from target cells. Therefore, hindering the effectiveness in long-term imaging of the cells (23, 32, 33). Indirect cell labeling methods have been introduced to overcome those problems. Although the mechanism is quite similar, it is more complicated and costly than direct cell labeling method. Target cells need to have an express of reported gene. Therefore, target cells need to be genetically modified before labeling with radiopharmaceuticals (23, 32).

### 2.2.3 Quality control of radiopharmaceuticals

Prior to patient administration, quality control procedures have to be performed to ensure optimum characteristic of synthesized radiopharmaceutical. Appearance is one of quality parameters, which is primarily verified by visual observations. pH measurement is normally performed using a pH strip (10). Some metals like Fe, Ni, Cu, Zn and Pb are used as components inside the column of the generator. These metals are impurity when they are co-eluted with a desired radioisotope out from the generator. They are normally determined by inductively coupled plasma-mass spectrometry (ICP-MS) (34). Radionuclidic purity, which is an amount of desired radionuclide in total radiopharmaceutical, is determined by using gamma spectroscopy (35). Radiochemical purity (RCP) is the amount of desired radiopharmaceutical in total radiopharmaceuticals. It is measured using radio HPLC, that has radioactivity detector, or TLC (36). In the case of TLC, the radioactivity TLC paper is measured by  $\gamma$  counter (Figure 5). The  $\gamma$  counter detects  $\gamma$  ray that interacts with its crystal. The interacting crystal emits light which is detected by the detector. The detected light was then amplified by photomultiplier. Finally, the light are

convert into electronic signal and then display on monitor screen (37). However, many of the tests cannot be performed before the administration due to limitation in physical half-life. Some of the tests like sterility and bacterial endotoxin test required considerable amount of time to complete (35). Therefore, radiopharmaceuticals are normally given to patients without waiting for sterility and bacterial endotoxin test results. To ensure safety, before administration of any radiopharmaceuticals to patient, it must be filtered by sterile filter. However, sterility tests using fluid thioglycolate medium and soybean-casein digest medium, and bacterial endotoxin test using limulus amoebocyte lysate test still needed to be done in order to keep record (38, 39).

### 2.3 Production and application of Gallium-68

Ga-68 is a positron-emitting radioisotope of gallium. Ga-68 mainly emits positrons (89%), with the highest energy at 1.9 MeV and the average energy at 0.91 MeV (40). Ga-68 decays to Zn-68 with a relatively short physical half-life of 68 minutes (Figure 6), which is suitable for clinical use (41, 42). Generally, the cost of production is relatively low due to the fact that Ga-68 does not necessarily require a cyclotron. It can be obtained from the  $^{68}\text{Ge}/^{68}\text{Ga}$  generator (Figure 7) using hydrochloric acid (HCl). Once Ga-68 is obtained in the form of  $^{68}\text{GaCl}_3$ , it will be in a trivalent form ( $\text{Ga}^{3+}$ ), which is capable of forming a stable complex with a chelator, such as DOTA through the chelation method. Ga-68 plays an important role in theranostic application because chelators like DOTA can also form complexes with Lu-177 and Ac-225 for therapeutic purposes (40-42). Ga-68 has shown many clinical uses, especially in oncology, such as for prostate cancer imaging using  $^{68}\text{Ga}$ -PSMA (Figure 8) which is a transmembrane glycoprotein enzyme that over-expresses on prostate cancer (43). Ga-68 can also be used in neuroendocrine tumor (NET) imaging which utilizes  $^{68}\text{Ga}$ -DOTA/NOTA-peptide like Tyr3-Octreotate (TATE)/Phe1-Tyr3-Octreotide (TOC)/NaI3-Octreotide (NOC) which are somatostatin analogs that bind to somatostatin receptors (SST) over-expressed on NET (44).

[https://en.wikipedia.org/wiki/File:Gallium\\_68\\_PSMA-11.jpg](https://en.wikipedia.org/wiki/File:Gallium_68_PSMA-11.jpg)

### 2.3.1 Production of Gallium-68 using $^{68}\text{Ge}/^{68}\text{Ga}$ generator

The easiest way to obtain Ga-68 is from the  $^{68}\text{Ge}/^{68}\text{Ga}$  generator. The parent radioisotope is germanium-68 (Ge-68), which has a relatively long physical half-life of 271 days. The first  $^{68}\text{Ge}/^{68}\text{Ga}$  generator was introduced around 1960 (46). To elute Ga-68, low concentration of ethylenediaminetetraacetic acid (EDTA) is required. The obtained Ga-68 is in form of  $^{68}\text{Ga}$ -EDTA. Nowadays, the Ga-68 is eluted by using low concentration of HCl (46). HCl interacts with Ga-68 inside the generator resulting in the product in form of  $^{68}\text{GaCl}_3$ . Consequently, the generator can continuously generate Ga-68 for a year (34, 41). However, the generator should be eluted every day or pre-elute 1 day before intended use in order to avoid Ge-68 breakthrough, which is a contaminant of Ge-68 in elution (34). Once Ga-68 is eluted from the generator, it is essential for the generator to undergo a waiting period until it nearly attains equilibrium before the elution process can be repeated. The equilibrium is the condition that daughter radioisotope concentration is equal to parent radioisotope concentration. In the specific case of Ge-68 and Ga-68 the equilibrium is called

secular equilibrium (Figure 9). The secular equilibrium is characterized by the parent radioisotope having a much longer physical half-life than daughter radioisotope (more than 100 times longer). This results in steady concentration of the parent radioisotope (47). Ga-68 has secular equilibrium at 14 h after the elution. However, it is not necessary to wait for 14 h in order to elute Ga-68 again. After 4 h post elution, the accumulation reaches over 90% and reach close to 100% after 6 h post elution. Therefore, if required the generator can be eluted every 4 h (34, 47).

**Figure 9.** Secular equilibrium of Ga-68 (48)

### 2.3.2 Production of Gallium-68 using cyclotron

Ga-68 can still be obtained through the  $^{68}\text{Zn}(p,n)^{68}\text{Ga}$  reaction using a cyclotron, with the option of employing either a solid or liquid target (10, 34). In case of liquid target, the target is Zn-68 solution typically in form of  $^{68}\text{Zn}(\text{NO}_3)_2$  or  $^{68}\text{ZnCl}_2$ . Generally,  $^{68}\text{Zn}(\text{NO}_3)_2$  is more preferred due to  $^{68}\text{ZnCl}_2$  can cause radiolysis to the overall Zn 68 solution (10). The target is bombarded by 12–14 MeV beam energy. The cyclotron feature water and helium as a cooling system to combat heat generated from the bombardment. The yield of Ga-68 is mainly dependent on the Zn-68 concentration and the pressure during the bombardment (10). In the case of solid

target, the target is a Zn-68 powder compressed in a pellet. The target is then bombarded with the same energy beam for liquid target. In general, Zn-68 solid target yield higher  $^{68}\text{GaCl}_3$  than the liquid counterpart due to its denser of Zn-68 in given area (10). The main disadvantage of using cyclotron in the production of Ga-68 is that the obtained product have to be purified to remove Zn-68 impurity, resulting in overall lower  $^{68}\text{GaCl}_3$  yield (34). Increasing of beam energy can increase Ga-68 yield, but it also increases unwanted Ga-67 which is not suitable for PET imaging due to it emits  $\gamma$  ray (10).

#### **2.4 Radiolysis and radiostabilizer**

Radiolysis or radiolytic degradation, is the degradation of compounds that prevents product formation caused by free radicals. Free radicals are induced by ionizing radiation, such as  $\alpha$ -,  $\beta$ - and  $\gamma$ -rays emitted from radionuclides (10, 49-51). A radiostabilizer, or radioprotectant, is a radical scavenger that can prevent the formation of free radicals (Figure 10). A good radiostabilizer should not interfere with the radiolabeling process, change the pH of solution, or interact with starting materials or radionuclides (49-51). There are some radiolabeling agents that are commonly used for radiolabeling processes, such as ascorbic acid, sodium ascorbate, acetate buffer, gentisic acid, etc. Due to each compound having different physical and chemical properties, selecting a suitable radiostabilizer is very important (10, 51). Therefore, it is worth considering which radiostabilizer is most suitable when developing new radiopharmaceuticals (10, 49-51).

**Figure 10.** Mechanism of ascorbic acid as an antioxidation (52)

## 2.5 PET imaging

PET is a non-invasive imaging technique in nuclear medicine. Not all radioisotopes are suitable for PET scans; only positron-emitting radioisotopes have the capability (Table 2). PET scan machine detects two gamma rays produced by the annihilation reaction by using a ring detector (Figure 11). An annihilation reaction is a reaction in which electrons in the subject body interact with positrons emitted from a radioisotope. This interaction produces two gamma rays with a tilt angle of 180 degrees and energy at 511 keV (53). The two gamma rays are detected by ring detector inside the scanner within a limited time window usually around 4 – 12 ns (27, 53). There are three types of coincidences that can occur in PET: true, scattered, and random coincidences. Only true coincidence is relevant for image reconstruction. The reconstruction is carried out by an algorithm like iterative reconstruction method (53). PET imaging is a highly sensitive imaging technique that can provide a series of 3D images (53, 54). This technique is useful in scientific research for tracking down the in vivo biodistribution of molecules of interest labeled with radionuclides in real time and in clinical applications such as oncology, neurology, cardiology, and infectious disease (53-55). The main downside of PET is its low spatial resolution around 5-7

mm (27, 56). To overcome this problem, PET is usually paired with CT (Figure 12) which not only provides accurate anatomical position, but also provides attenuation value based on the attenuation coefficient of different tissues (27, 56). CT scan is a bore-shape instrument like PET scan. It consists of X-ray tube and detector with 180 degrees tilt angle. The tube and detector rotate simultaneously during image acquisition (56). CT usually generates photons with energy around 100 – 150 keV. Therefore, the obtained attenuation value needs to be scaled up to 511 keV for PET image attenuation correction (27, 56).

Iodine-124	4.2 days	Positron, electron capture	Cyclotron

## Chapter III

### Materials and Methods

#### 3.1 Materials

$\alpha$ CD was kindly donated by Wacker Chemie (Munich, Germany). Soluble  $\alpha$ CD polymer crosslinked with epichlorohydrin was purchased from Cyclolab R&D (Budapest, Hungary). Miconazole was purchased from Fagron group B.V., (Rotterdam, the Netherlands). Cyclosporin A was purchased from GenWay BioTech Inc. (San Diego, USA). Ga-68 solution was eluted from ITM  $^{68}\text{Ge}/^{68}\text{Ga}$  generator (radiochemical grade). 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) was purchased from Chematech (Dijon, France). Sodium ascorbate was purchased from Tokyo Chemical Industry (Tokyo, Japan). Ascorbic acid was purchased from MySkinRecipes (Bangkok, Thailand). Sep-Pak C-18 cartridges were purchased from Waters (Massachusetts, USA). Other chemical reagents were provided by the Division of Nuclear Medicine, Department of Radiology, Faculty of Medicine, Siriraj Hospital, Mahidol University.

#### 3.2 Methods

##### 3.2.1 Radiosynthesis of $^{68}\text{Ga}$ -DOTA and $^{68}\text{Ga}$ - $\alpha$ CD

The radiosynthesis procedure is modified based on the clinical use of the PSMA-11 radiolabeling protocol (57). In this study,  $\alpha$ CD was used as a ligand due to its high aqueous solubility and can be used in various pharmaceutical dosage forms, especially in parenteral solution (58). Briefly, 250 mg of  $\alpha$ CD was accurately weighed, dissolved, and adjusted with sterile water to 100 mL (2.5 mg/ml). Further dilution was prepared by pipetting 1 ml of obtained  $\alpha$ CD solution into a 10-ml volumetric flask and then adjusting the volume with sterile water to obtain the final concentration (0.25 mg/ml). After that, 100  $\mu$ l of  $\alpha$ CD solution was pipetted and mixed with 2 ml of 0.05 M HCl in a syringe. To compared with the reference, DOTA, the most commonly used as a chelator for Ga-68 (Figure 13) was prepared with the same procedure as described above (59).

For the Ga-68 eluting process, the reaction vial was put in shielding and connected to the  $^{68}\text{Ge}/^{68}\text{Ga}$  generator. Then, Ga-68 was eluted from the generator by using 4 ml of 0.05M HCL as an eluent. Radioactivity was measured immediately after

the elution. The obtained  $^{68}\text{GaCl}_3$  solution was divided into two reaction vials. DOTA and  $\alpha\text{CD}$  solutions that were previously prepared were separately added to the reaction vial. Both vials were heated at  $100\text{ }^\circ\text{C}$  for 20 minutes. After that, the reaction was allowed to cool down at room temperature for 5 minutes. Finally, the radioactivity was measured using instant thin layer chromatography (iTLC), and the presenting result data was RCP (Figure 14 and 15). Each sample was performed in triplicate.

**Figure 13.**  $^{68}\text{Ga}$ -DOTA structure

**Figure 14.** Radiosynthesis of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$

**Figure 15.** Chemical reaction during radiosynthesis of  ${}^{68}\text{Ga-DOTA}$  and  ${}^{68}\text{Ga-}\alpha\text{CD}$

### 3.2.2 Optimization of radiosynthesis

To optimize the radiosynthesis, the effect of radiostabilizers on the RCP of the  ${}^{68}\text{Ga-DOTA}$  and  ${}^{68}\text{Ga-}\alpha\text{CD}$ , various  $\alpha\text{CD}$  concentrations and the use of its derivative, soluble  $\alpha\text{CD}$  polymer were determined on the RCP of  ${}^{68}\text{Ga-}\alpha\text{CD}$ , and finally, the purification step using C-18 cartridge was performed.

#### 3.2.2.1 Effect of radiostabilizer

Sodium ascorbate and ascorbic acid were selected as radiostabilizers. These two radiostabilizers have been reported as effective radiostabilizers for many radiopharmaceuticals (60). Each compound was separately prepared by dissolving 0.04 g in 2 ml of sterile water. Each solution was mixed with 100  $\mu\text{l}$  of DOTA or  $\alpha\text{CD}$  solutions and used as a ligand sample. The radiosynthesis process was conducted as described above. Each sample was performed in triplicate.

#### 3.2.2.2 Effect of $\alpha\text{CD}$ concentration and $\alpha\text{CD}$ polymer

A stock solution of  $\alpha\text{CD}$  was prepared by dissolving 500 mg of  $\alpha\text{CD}$  in 100 ml of sterile water (5.0 mg/ml). Serial dilutions of  $\alpha\text{CD}$  solutions were prepared, and the concentration range from 0.5 to 5.0 mg/ml were given. To assess the effect of three-dimensional polymer on degree of radiolabeling, 50 mg of soluble  $\alpha\text{CD}$  polymer crosslinked with epichlorohydrin was accurately weighed, dissolved, and adjusted with sterile water to 50 ml (1 mg/ml). 100  $\mu\text{l}$  of resulting  $\alpha\text{CD}$  solution or  $\alpha\text{CD}$  polymer was mixed with 2 ml of sodium ascorbate solution (2% w/v). The

radiosynthesis process was conducted as described above. Each sample was performed in triplicate.

### 3.2.2.3 Purification of $^{68}\text{Ga-}\alpha\text{CD}$

$^{68}\text{Ga-}\alpha\text{CD}$  was purified by C-18 cartridge. Firstly, the C-18 cartridge was washed with 2 ml ethanol prior to radiosynthesis process. After the radiosynthesis, waste vial was put in shielding and connected to the C-18 cartridge.  $^{68}\text{Ga-}\alpha\text{CD}$  solution in reaction vial was drawn via syringe and connected to C-18 cartridge. The solution was pushed slowly through the C-18 cartridge. Subsequently, the C-18 cartridge was transferred to connect with product vial, which is in another shielding. C-18 cartridge was slowly flushed with 3 ml of 1:1 ethanol:water. Finally, the radioactivity and RCP of solution from product and waste vials were determined.

## 3.2.3 Chemical analysis

### 3.2.3.1 TLC and RCP determination

0.2 ml of sample ( $^{68}\text{Ga-DOA}$  or  $^{68}\text{Ga-}\alpha\text{CD}$ ) were drawn in 1-ml syringe. Five small drops of the sample solution were dropped on iTLC paper. The paper was placed in a mobile phase tank containing 1 ml of 1:1 ammonium acetate:methanol. To determine TLC, the iTLC papers were scanned by TLC scanner (Gamma BGO-V-Detector, Raytest®, Isotopenmessgeraette, GmbH, Germany). For RCP measurement, the paper was cut into eight sections and put in eight separate tubes. After that, the activity of iTLC paper was measured in a well-chambered  $\gamma$ -counter. The RCP of the obtained product was calculated using the following equation:

$$\text{RCP} = (\text{Product} / [\text{Product} + \text{Free Ga-68}]) \times 100$$

### 3.2.3.2 Mass spectrometry

Qualitative analysis of  $^{68}\text{Ga-}\alpha\text{CD}$  involved determining the mass-to-charge ratio ( $m/z$ ) of  $^{68}\text{Zn-}\alpha\text{CD}$  by MS after 3 days of radiolabeling. This time frame ensured the complete decay of all Ga-68 into Zn-68. The sample was analyzed by ESI (+) triple quadrupole MS (QTRAP6500, Sciex, Framingham, MA, USA) and DART (+) time of flight MS (AccuTOF™ LC-Express Time-of-Flight Mass Spectrometer, JEOL, USA). In the case of ESI (+) triple quadrupole MS,  $^{68}\text{Ga-}\alpha\text{CD}$  was placed directly at ESI source and the analysis conditions were as follows: electrospray

ionization (ESI) positive mode; scan, 200–1050 m/z; temperature, 350 °C; capillary voltage, 4500 V; and collision energy, 40 eV. In the case of DART (+) time of flight MS,  $^{68}\text{Ga}-\alpha\text{CD}$  was placed directly at DART source and the analysis conditions were as follows: DART positive mode; scan, 200–1050 m/z; helium gas temperature, 350 °C; detector voltage, 2000 V; ion guide RF voltage, 600 V; reflection voltage, 960 V; flight tube voltage' 7000 V and orifice voltage, 10-90 V. The expected mass-to-charge ratio is 1041.3 g/mol  $^{68}\text{Ga}-\alpha\text{CD}$ .

### 3.2.3.3 pH measurement

pH of the obtained sample was determined using a pH meter (FE20 FiveEasy, Mettler Toledo, Switzerland) at 25 °C. Prior to analysis, the pH meter was calibrated with the standard solutions at the pH of 4, 7 and 10.

### 3.2.4 *In silico* computational study using Quantum Mechanics

The initial structure of  $\alpha\text{CD}$  was obtained from PDB (ID: 7uww), illustrated in Figure 16. The gallium ( $\text{Ga}^{3+}$ ) cation was placed on both primary and secondary rim of  $\alpha\text{CD}$  and four water molecules were added explicitly by using GaussView 6.0. The computations were performed using the Gaussian 09 software suite. Optimal geometries for all studied systems were obtained using density functional theory (DFT) by applying the UB3LYP level of theory (61) with a 6-31G (d, p) basis set. To conduct computations in aqueous environments, the Conductor-Like Polarizable Continuum Model (CPCM) is commonly employed as a water model. This PCM variant incorporates the charge-transfer effect as an integral aspect of solvation (62). Adsorption energy, an energy required for a molecule or a system to absorb a photon and undergo electronic excitation (63) was calculated for ternary complexes using the following equation.

$$E_{ads} = E_{n\text{H}_2\text{O}/\text{Ga}-\alpha\text{CD}}^{tot} - E_{n\text{H}_2\text{O}}^{tot} - E_{\text{Ga}-\alpha\text{CD}}^{tot}$$

Where  $E_{n\text{H}_2\text{O}/\text{Ga}-\alpha\text{CD}}^{tot}$  is the total energy of the adsorption system,  $E_{n\text{H}_2\text{O}}^{tot}$  is the total energy of the intact water molecules and  $E_{\text{Ga}-\alpha\text{CD}}^{tot}$  is the energy of binary complex of  $\text{Ga}-\alpha\text{CD}$ .

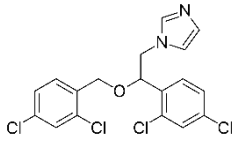

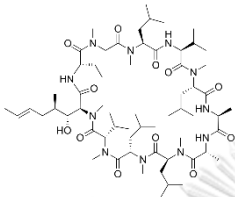

**Figure 16.** 3D structure of  $\alpha$ CD (a) top view (b) side view representing primary and secondary rim.

### 3.2.5 Effect of guest molecules on the RCP and binding properties

To determine the drug binding capacity of neat  $\alpha$ CD and  $^{68}\text{Ga}$ - $\alpha$ CD, miconazole and cyclosporin A were selected as guest molecules because they favor  $\alpha$ CD cavity and are representative of small and large molecular weight, respectively (64, 65). The chemical structures and physicochemical properties of miconazole and cyclosporin A are present in Table 3. Briefly, an excess amount of miconazole or cyclosporin A was added to  $\alpha$ CD solution (1% w/v) to obtain drug saturation. The obtained drug suspension was agitated in an incubation shaker at  $30 \pm 1$  °C, 150 rpm, for 24 h. After equilibrium is attained, 100  $\mu\text{l}$  of each sample was pipetted and then mixed with 2 ml of 2% (w/v) sodium ascorbate solution. Finally, the sample was subjected to the radiolabeling process as previously described.

**Table 3.** Chemical structure and physicochemical properties of miconazole and cyclosporin A

Drug	Chemical structure	Molecular weight (g/mol)	Log P	Solubility in water at 25 °C	Ref.
Miconazole		416.1	5.86	0.7 µg/ml	(66)
Cyclosporin A		1202.6	2.92	27 µg/ml	(67, 68)

### 3.2.6 Statistical analysis

All quantitative data are presented as the mean  $\pm$  standard deviation (SD). The statistical significance of the difference in mean was calculated by paired T test or one-way ANOVA followed by Post Hoc test. A  $p < 0.01$  was considered as statistical significance.

## Chapter IV

### Results and Discussion

#### 4.1 Identification and characterization of $^{68}\text{Ga-}\alpha\text{CD}$

##### 4.1.1 Mass spectrometry

As described earlier, Ga-68 completely decayed into Zn-68, and thus MS of  $^{68}\text{Ga-}\alpha\text{CD}$  was determined in form of  $^{68}\text{Zn-}\alpha\text{CD}$ . Since Zn-68 has a molecular weight of 68 and  $\alpha\text{CD}$  has molecular weight of 972.3, the expected mass-to-charge ratio of  $^{68}\text{Zn-}\alpha\text{CD}$  is 1041.3 Da, assuming that the final product ( $^{68}\text{Zn-}\alpha\text{CD}$ ) is 1:1 complex. The mass-to-charge of  $^{68}\text{Zn-}\alpha\text{CD}$  in different ratios is shown in Table 4. Each  $m/z$  value is calculated by the following equation (69):

$$(m/z) = [M + zmH^+]/z$$

Where M is monoisotopic mass,  $mH^+$  = proton mass and z is charge state.

ESI is an ionization technique in mass spectrometry. The electrostatic spray the injected solution in high electric field at the capillary tip, leading to the formation of a fine aerosol of charged droplets (70). Figure 17A shows the full ESI (+) triple quadrupole MS spectrum of the samples. A peak at 261.1 Da is observed which is aligned with the calculated  $m/z [1040.3 + (4 \times 1)]/4 = 261.08$ , representing a 1:1 complex of  $^{68}\text{Zn-}\alpha\text{CD} (M + 4H)^{4+}$ . No other complexations, e.g., 1:2 or 1:3 complex was found.

**Table 4.** Mass-to-charge of  $^{68}\text{Zn}$ - $\alpha\text{CD}$  in different ratios.

Charge value	Mass-to-charge of $^{68}\text{Zn}$ - $\alpha\text{CD}$ (Da)				
	1:1	2:1	3:1	1:2	1:3
1	1041.3	1109.3	1177.3	2013.6	2850.9
2	521.15	555.15	589.15	1007.3	1425.95
3	347.77	370.43	393.1	671.87	950.97

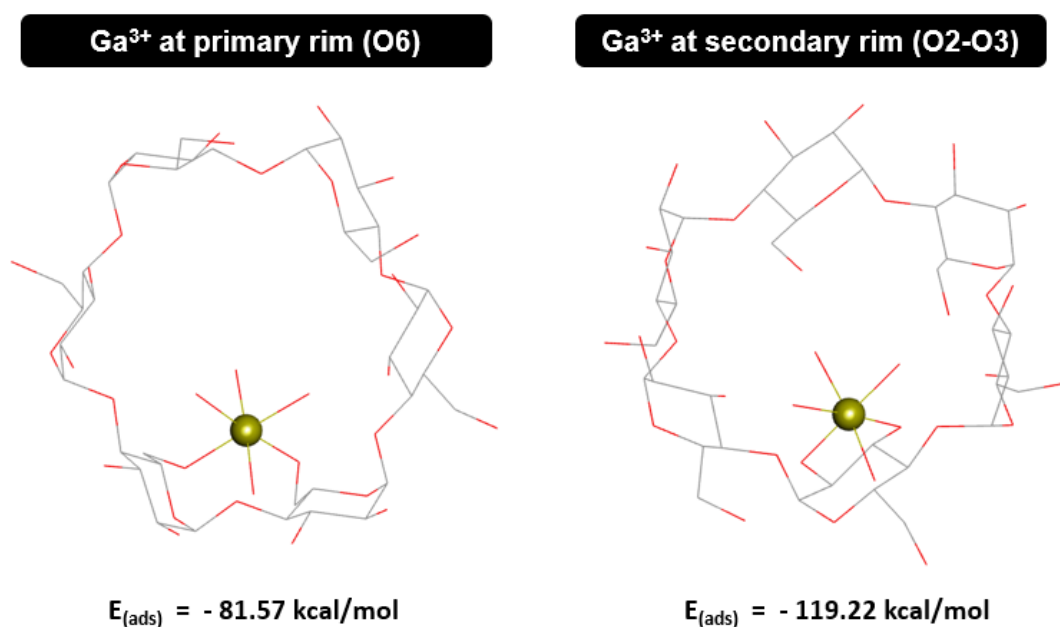

**Figure 17.** ESI (+) triple quadrupole MS spectrum (A) and DART (+) time of flight MS spectrum (B) of  $^{68}\text{Zn-}\alpha\text{CD}$

DART is another ionization technique in MS. It uses a stream of gas, like Helium, to interact with the sample. This interaction generates ions from the sample surface, which are then introduced into the mass spectrometer for analysis (71). Figure 17B shows DART (+) time of flight MS. The peak at 521.15 Da is observed, which is aligned with the calculated  $m/z$   $[1040.3+(2 \times 1)]/2 = 521.15$  Da, representing a 1:1 complex of  $^{68}\text{Zn-}\alpha\text{CD}$   $(M+2H)^{2+}$ . The obtained results from both MS supported that  $^{68}\text{Ga-}\alpha\text{CD}$  was formed with the stoichiometry ratio of 1:1 complex of  $^{68}\text{Zn-}\alpha\text{CD}$  in the final solution.

#### 4.1.2 *In silico* computational study

Theoretical methods, particularly spin-unrestricted density functional theory (UDFT) calculations, have played a crucial role in providing insights into the electronic structure of active species and plausible reaction mechanisms (72). We used CPCM as an implicit water model to evaluate the behavior of complexes in an aqueous environment. The result shows that  $\text{Ga}^{3+}$  interacted with four explicit water molecules and two O6 at the primary rim and O2-O3 at the secondary rim of  $\alpha\text{CD}$ , depicted in Figure 18, making a total of six coordination numbers which is in agreement with the reported study (73). There is a significant difference between the adsorption energies of  $\text{Ga}^{3+}$  at the primary rim (- 81.57 kcal/mol) and secondary rim (- 119.22 kcal/mol), which could be due to electrostatic interactions and hydrogen bonding in the implicit aqueous medium (74, 75). These findings are consistent with the MS data, indicating that Ga-68 has an affinity for  $\alpha\text{CD}$  with a stoichiometry ratio of 1:1 in the complex.

**Figure 18.** Top view of complexes with  $\text{Ga}^{3+}$  cation.

The CD skeletons are depicted as wireframes, while the metal cations are represented as spheres, connected with four water molecules.

#### 4.2 Optimization of radiosynthesis of $^{68}\text{Ga}$ -DOTA and $^{68}\text{Ga}$ - $\alpha\text{CD}$

Table 5 displays the pH and the RCP of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  in the presence and absence of radiostabilizer. In the absence of radiostabilizer, the RCP of both samples are relatively low. As expected, the RCP of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  was 13.68% and 0.24%, respectively. According to diluted HCl as a solvent of both  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$ , the solutions were highly acidic with the pH of 1.55 and 1.56, respectively. To improve the RCP of these synthesized compounds, the addition of radiostabilizer was further investigated.

**Table 5.** pH and the radiochemical purity of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$

Radiopharmaceuti cals	Radiostabilizer	pH	Radiochemical purity (RCP, %)	RCP ratio <sup>a</sup>
$^{68}\text{Ga}$ -DOTA	-	1.55 ± 0.03	13.68 ± 0.69%	-
	Ascorbic acid	2.02 ± 0.12	60.57 ± 5.68%*	4.43
	Sodium ascorbate	3.83 ± 0.29	94.56 ± 1.34%*	6.91
$^{68}\text{Ga}$ - $\alpha\text{CD}$	-	1.56 ± 0.02	0.24 ± 0.03%	-
	Ascorbic acid	2.07 ± 0.23	0.59 ± 0.29%	2.46
	Sodium ascorbate	3.93 ± 0.19	4.19 ± 0.25%*	17.46

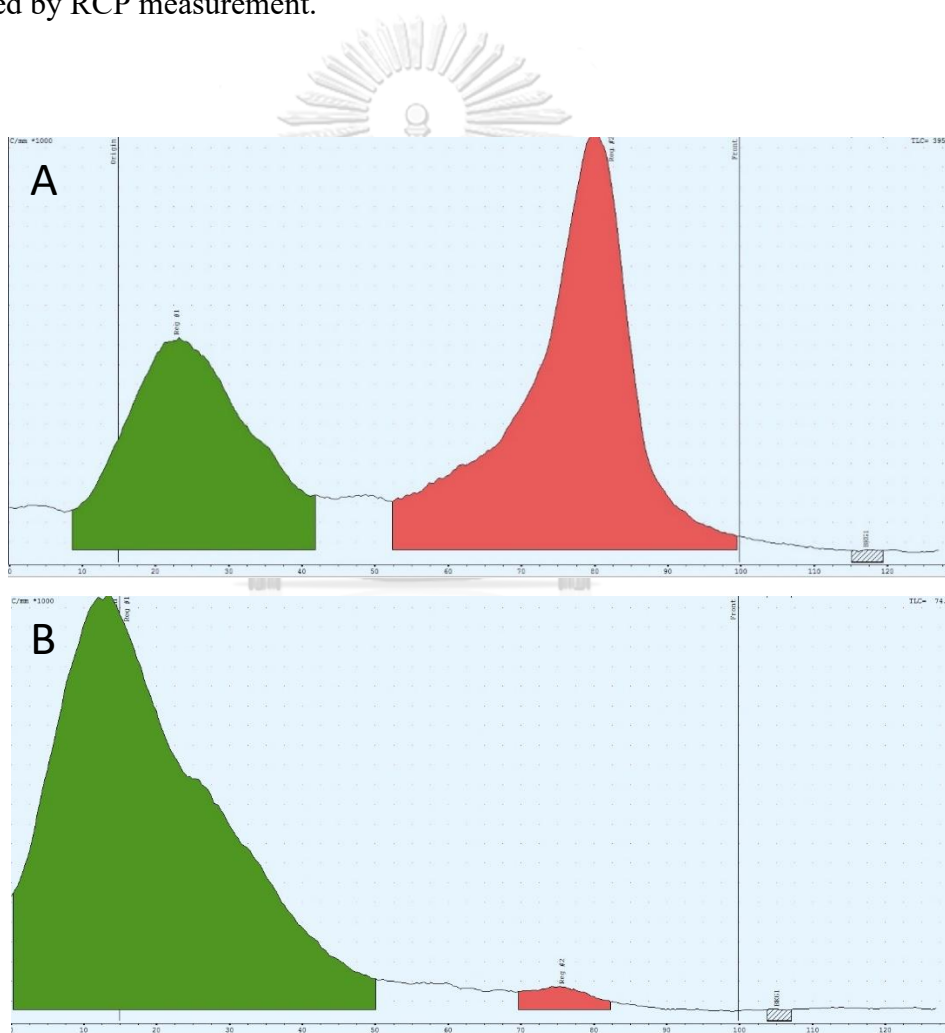

<sup>a</sup> ratio of RCP of the sample in presence of radiostabilizer/the absence of radiostabilizer. \*Statistical difference (\*  $p < 0.01$ ) when compared to the absence of radiostabilizer

##### 4.2.1 Effect of radiostabilizers

In both cases ( $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$ ), the RCP obtained from sodium ascorbate as a radiostabilizer yields significantly higher than those of ascorbic acid ( $p < 0.01$ ), followed by those of without radiostabilizer. It indicates that radiostabilizer has a strongly positive effect on RCP in the radiolabeling process. A radiostabilizer also known as radioprotectant, is a radical scavenger that can prevent the formation of free radicals, which are induced by radiation emitted from radionuclide. These free radicals can degrade compounds or prevention formation of desired product (10, 49-51). Regarding to the pH of solutions, in the presence of ascorbic acid, the pH of

$^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  solutions were about 2.0, while that of sodium ascorbate were significantly higher (3.8–4.0) compared to the former cases ( $p < 0.01$ ). Baudhuin et al. (50) investigated the effect of various radiostabilizers on  $^{68}\text{Ga}$ -NOTA-single-domain antibodies radiolabeling. Their result indicates ascorbic acid and gentisic acid are not well compatible with Ga-68. Based on our results, it clearly demonstrated that ascorbic acid was less potent than sodium ascorbate. This was assumed that the obtained RCP possibly be related to the pH of the sample. Optimal pH range for Ga-68 radiolabeling is ranging from 3 to 5 (76, 77). At pH lower than 3, the solution is too acidic for radiolabeling, whereas at pH above 5,  $^{68}\text{GaCl}_3$  forms complex with hydroxide and become  $^{68}\text{Ga}(\text{OH})_3$ , which is incapable of radiolabeling (76). Thus, in our case, the pH of the samples that comprise of sodium ascorbate are within the optimum range, which is suitable for Ga-68 radiolabeling, especially in case of  $^{68}\text{Ga}$ -DOTA exhibited the RCP value up to 95%. Our findings strengthen the strong binding affinity between DOTA and Ga-68. DOTA is a very well-known and commonly used bifunctional chelator for radiometal in nuclear medicine. Its cyclic structure offers an exceptional binding affinity with high thermodynamic stability. This ensures that once the radiometal is chelated inside, it remains securely bound without dissociated (78, 79). Interestingly, our synthesized  $^{68}\text{Ga}$ - $\alpha\text{CD}$  using sodium ascorbate as a potent radiostabilizer could generate 17.5 times higher than that using ascorbic acid. Sodium ascorbate, acting as an antioxidant, is biocompatible and also possesses a neutral and non-toxic substance. As the sodium salt of ascorbic acid, it is a water-soluble compound exhibiting potent antioxidant properties with low toxicity (80, 81). In order to confirm that sodium ascorbate does not compete with  $\alpha\text{CD}$  or DOTA in radiosynthesis process, radiolabeling of  $^{68}\text{GaCl}_3$  and sodium ascorbate (without ligand i.e, DOTA or  $\alpha\text{CD}$ ) was carried out. The result showed that the pH of final solution was about 2, which was not the optimal pH for radiolabeling and there was barely any activity on the product section of iTLC paper (RCP  $\approx$  0.01%). This indicates that sodium ascorbate did not interact with  $^{68}\text{GaCl}_3$ . Because  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  using sodium ascorbate as a radiostabilizer showed a promising RCP result, their iTLC papers were further scanned by TLC scanner. Figure 19A and B display thin layer chromatograms of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$ , respectively. The products namely  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  were shown in red, while free Ga-68 was

shown in green. Retention factor (Rf) of  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  were 0.77 and 0.72, respectively. The results from the scanner are aligned with the RCP,  $^{68}\text{Ga}$ -DOTA shows the product yield larger than free Ga-68. This is attributed to the strong preference of  $\text{Ga}^{3+}$  ions for the DOTA cavity (79). In contrast,  $^{68}\text{Ga}$ - $\alpha\text{CD}$  exhibited a large amount of free Ga-68 together with low product yield. This is likely because the Ga-68 does not bind firmly to  $\alpha\text{CD}$  like it does with the DOTA. This is supported by the result from *in silico* computational study which reveals that Ga-68 binds two OH groups of  $\alpha\text{CD}$  and four water molecules. These observations support the result obtained by RCP measurement.

**Figure 19.** Thin layer chromatograms of  $^{68}\text{Ga}$ -DOTA (A) and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  (B). The products that are  $^{68}\text{Ga}$ -DOTA and  $^{68}\text{Ga}$ - $\alpha\text{CD}$  are present in red (A and B, respectively), while free Ga-68 is present in green.

#### 4.2.2 Effect of $\alpha$ CD concentrations and $\alpha$ CD polymer

The effect of  $\alpha$ CD concentrations as a ligand on RCP of  $^{68}\text{Ga}$ - $\alpha$ CD was determined for the optimization parameter of radiosynthesis. The  $\alpha$ CD concentration used in the study ranged from 2 to 20-folds compared to the initial step. Figure 16 displays the effect of  $\alpha$ CD concentrations on the RCP of  $^{68}\text{Ga}$ - $\alpha$ CD. It divided into two parts where the RCP was increased with increasing  $\alpha$ CD until its concentration of 1 mg/ml, which yielded the highest RCP ( $6.18 \pm 0.16\%$ ) and then levelling off. This assumes that the saturation between  $\text{Ga}^{3+}$  ion and ligand has been attained.  $\alpha$ CD concentrations at 0.5 mg/ml and 1 mg/ml did not show a significant difference in RCP ( $p > 0.01$ ). However, 1 mg/ml  $\alpha$ CD was selected for further studies because it yielded the highest RCP. Comparison between each  $\alpha$ CD concentration was shown in figure 20.

**Figure 20.** The effect of concentrations of  $\alpha$ CD on the radiochemical purity of  $^{68}\text{Ga}$ - $\alpha$ CD. \*Statistical difference (\* $p < 0.01$ ) when compared to the initial  $\alpha$ CD concentration (0.25 mg/ml).

To assess the impact of its three-dimensional configuration on labeling affinity with Ga-68,  $\alpha$ CD polymer crosslinked with epichlorohydrin at the same concentration as  $\alpha$ CD (1 mg/ml) was used. Epichlorohydrin is a widely used cross-linking agent. It forms the bond with CDs at the OH group on either primary or secondary rim. The polymerization of CDs with epichlorohydrin results in the creation of a 3D polymer network. This network offer an effective enhancement in drug delivery, contributing to the improved solubility and bioavailability of encapsulated drugs (82). The preliminary results reveal a pH value of  $4.12 \pm 0.2$  and an obtained RCP of  $5.49 \pm 0.57\%$ . This resulting RCP is slightly lower than that achieved with the 1 mg/ml  $\alpha$ CD solution ( $6.18 \pm 0.16\%$ ). Although the CD polymer has additional binding sites derived from the polymer network, it appears that Ga-68 cannot bind within this polymer network. Instead, the substituent groups (i.e., epichlorohydrin) may hinder Ga-68 from binding to O6 at the primary rim and O2-O3 at the secondary rim of  $\alpha$ CD. However, further studies are required to support this assumption. Nevertheless, given the lack of a significant difference in RCP between  $\alpha$ CD and its polymer,  $\alpha$ CD polymer was discarded for further studies.

#### 4.2.3 Purification of $^{68}\text{Ga}-\alpha\text{CD}$

It was found that the utilization of a C-18 cartridge for purification is a notable increase in the RCP. C-18 cartridge is a commonly used as a solid phase extraction cartridge for Ga-68 purification in clinical settings (10). C-18 cartridge comprises of octadecyl alkyl hydrocarbon chain (C18) which binds to the silica material and provides the column with hydrophobic properties, enabling the cartridge to trap non-polar or low polar compound inside the cartridge while allowing polar compound to pass through (83). Thus, the C-18 is able to trap our desired product ( $^{68}\text{Ga}-\alpha\text{CD}$ ) inside the column while free Ga-68 is discarded into waste vial. To get the desired product, C-18 will be eluted with solvents like ethanol and water (10). The final product after elution has a pH of  $4.90 \pm 0.08$  which is higher than that form the unloaded C-18 cartridge that has pH value of  $4.12 \pm 0.2$ . Acidic pH likely due from hydrogen ions ( $\text{H}^+$ ) not being trapped inside the hydrophobic cartridge of C-18, allowing them to pass through and enter directly into the waste vial. This is consistent with the pH value of the waste vial which demonstrates a pH level of  $4.12 \pm 0.06$ ,

closely resembling the condition without the loading of C-18. The final RCP of  $^{68}\text{Ga}$ - $\alpha\text{CD}$  is  $18.42 \pm 1.07\%$ , which is a three-fold increase compared to no further purification step ( $6.18 \pm 0.16\%$ ), ( $p < 0.01$ ). Despite the final RCP showing notable increases, it falls extremely below when compared to  $^{68}\text{Ga}$ -DOTA, which is able to achieve an impressive RCP of  $94.56 \pm 1.34\%$  without any purification. The lower RCP observed in  $^{68}\text{Ga}$ - $\alpha\text{CD}$  may be attributed to the presence of some free Ga-68 within the product vial, potentially resulting from a high influx of free Ga-68, an incomplete separation between free Ga-68 and  $^{68}\text{Ga}$ - $\alpha\text{CD}$ , or the dissociation of some  $^{68}\text{Ga}$ - $\alpha\text{CD}$  back into free Ga-68.

According to the studies by Fuscaldi et al (57) the automatic synthesis module was employed to synthesize  $^{68}\text{Ga}$ -PSMA-11. Using the similar protocol of our study, they are able to achieve a remarkably high RCP at 95.59% with the use of a C-18 cartridge. This indicates that despite the C-18 cartridge having been proven itself several times in numerous clinical settings, it might not be the most optimal choice for  $^{68}\text{Ga}$ - $\alpha\text{CD}$  purification. According to the literature Ga-68 radiopharmaceutical RCP should exceed 90% in order to be applied in clinical setting (10, 57). Therefore, consideration of additional purification steps or exploring new techniques are required to achieve a higher RCP of  $^{68}\text{Ga}$ - $\alpha\text{CD}$ .

One of the potential approaches involves the utilization of size exclusion chromatography, which is also known as gel filtration chromatography. It is a commonly used technique to purify and separate different compounds based on their size distinction (84). In size exclusion chromatography, a porous material serves as the stationary phase. Small molecular compounds will fit within porous pore of stationary phase while large molecular compounds do not enter the pores and eluted through the column more rapidly (84). Consequently, molecules separate based on their size as they pass through the column and are eluted in order to decrease MW. The implementation of the size exclusion chromatography as a purification column could potentially help increase RCP of  $^{68}\text{Ga}$ - $\alpha\text{CD}$ . Its ability to retain small molecular compounds allows for the capture of unreacted free Ga-68 inside the column, while larger  $^{68}\text{Ga}$ - $\alpha\text{CD}$  passes through the column. Employing the size exclusion chromatography as a preliminary step before employing C-18 cartridge could

potentially alleviate the influx of free Ga-68 into subsequent purification step. Alternatively, it can be employed as a stand-alone method, letting it capture unreacted free Ga-68 and allowing the collection of pass-through fractions containing purified  $^{68}\text{Ga-}\alpha\text{CD}$ .

Another potential approach is the utilization of ion exchange chromatography, a technique specifically designed for purification and separation of charge compounds from different charge or non-charge compounds. Its principle is based on electrostatic interaction between the compound and the stationary phase (85). There are mainly two types of ion exchange chromatography which are cation and anion exchange chromatography. The cation exchange chromatography is comprised of negatively charged stationary phase which interact and retain positively charged compound in the interested product. On the other hand, the anion exchange chromatography featuring positively charge stationary phase which interact and retain negatively charged compound (85). Employing the cation exchange chromatography could potentially help increase RCP of  $^{68}\text{Ga-}\alpha\text{CD}$ . Its ability to retain positive charge compound can be used to trap unreacted free Ga-68, while  $^{68}\text{Ga-}\alpha\text{CD}$  is freely transverse through the column.

Employing the size exclusion or cation exchange chromatography as a preliminary step before employing C-18 cartridge could potentially alleviate the influx of free Ga-68 into subsequent purification step. Alternatively, either size exclusion or cation exchange chromatography can be employed as a stand-alone method, allowing the column to effectively capture unreacted free Ga-68, facilitating the collection of a fraction that contains purified  $^{68}\text{Ga-}\alpha\text{CD}$ .

#### **4.3 Effect of guest molecules on the RCP of $^{68}\text{Ga-}\alpha\text{CD}$**

According to the literature, Jóhannsdóttir and co-workers investigated the phase-solubility profiles of cyclosporin A and various CD types. It was found that  $\alpha\text{CD}$  has greater solubilizing effect on cyclosporin A and provides higher complexing efficacy than the other CD tested (65). Fukuya et. Al (86) investigated the solubility and therapeutic effect of cyclosporin A/CD complex in inhalation dosage form for

asthma therapy. It was found that maltosyl- $\alpha$ CD (G2- $\alpha$ CD) was the most optimal choice for cyclosporin A/CD complex in inhalation dosage form. This CD inclusion complex provides solubilization enhancement, shows cilio-inhibition activity with low cytotoxicity. These observations demonstrate that cyclosporin A has higher affinity to CDs with relatively small cavities, forming water-soluble cyclosporin A/ $\alpha$ CD complexes than larger CD cavities. In the case of miconazole/CD complexes, Tenjarla and co-worker investigated the CD solubilizing effect of miconazole for oral and topical delivery. The complex was prepared by lyophilization method. It was found that  $\alpha$ CD significantly enhanced the aqueous solubility of miconazole compared to the larger CD cavities and their hydroxypropyl derivatives (i.e.,  $\beta$ CD,  $\gamma$ CD, HP $\beta$ CD and HP $\gamma$ CD) (64). Murata et. al (87) investigated the solubility effect of various CDs on miconazole for oral Candidiasis treatment. It was found that  $\alpha$ CD has a great solubilizer for miconazole, resulting in a 1.5-fold increase in its solubility. This demonstrates that miconazole also has higher affinity to CDs with relatively small cavities like  $\alpha$ CD. Thus, cyclosporin A and miconazole were selected as model drugs due to that they have affinity to  $\alpha$ CD cavity, and they can be used for parenteral preparations. Regards to molecular weight of cyclosporin A is 1202.6 Da (88) and that of miconazole is 416.13 Da (89), representing large and small molecule, respectively, the effect of these drugs on the RCP of  $^{68}\text{Ga}$ - $\alpha$ CD was further determined.

Table 6 shows pH and the RCP of  $^{68}\text{Ga}$ -miconazole- $\alpha$ CD and  $^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD complexes. The radiolabeling of miconazole- $\alpha$ CD and cyclosporin A- $\alpha$ CD complexes results in RCP that insignificantly difference compared to the neat  $^{68}\text{Ga}$ - $\alpha$ CD.  $^{68}\text{Ga}$ -miconazole- $\alpha$ CD complex demonstrates an RCP of  $18.68 \pm 1.69\%$ , whereas  $^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD complex exhibits an RCP of  $19.19 \pm 1.35\%$ . For the pH of solutions, it also has shown that with and without drugs, the pH was not altered. These findings indicate that the encapsulation of drugs within  $\alpha$ CD cavity does not interfere with the  $\text{Ga}^{3+}$  ion binding affinity.

*In silico* computational data as shown in Figure 18 support the effect of miconazole and cyclosporin A on binding affinity between Ga-68 and  $\alpha$ CD. Given that Ga-68 can bind to the either primary or secondary rim of  $\alpha$ CD, while either

miconazole or cyclosporin A bind inside the  $\alpha$ CD cavity. The RCP of  $^{68}\text{Ga}$ -miconazole- $\alpha$ CD and  $^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD are aligned with drug free  $^{68}\text{Ga}$ - $\alpha$ CD. Overall, the proposed  $^{68}\text{Ga}$ -miconazole- $\alpha$ CD and  $^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD configurations are shown in Figure 21. Additionally, this finding emphasizes the significant potential of  $^{68}\text{Ga}$ - $\alpha$ CD for further exploration, assuming that small or large drug molecules can be used to co-deliver with  $^{68}\text{Ga}$ - $\alpha$ CD. This presents a valuable avenue for gaining insight into the biodistribution and pharmacokinetic data of the specific drug. Moreover, our findings also pioneered present the possibility for therapeutic application, especially in cancer treatment. It is suggested that substituting Ga-68 with Lu-177 and employed alongside cancer drug might offer a synergistic effect on treatment of cancer.

**Table 6.** pH and the radiochemical purity of  $^{68}\text{Ga}$ -miconazole- $\alpha$ CD and  $^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD complexes

Radiopharmaceuticals	pH	Radiochemical purity (RCP, %)	RCP ratio <sup>a</sup>
$^{68}\text{Ga}$ - $\alpha$ CD	$4.90 \pm 0.08$	$18.42 \pm 1.07\%$	-
$^{68}\text{Ga}$ -miconazole- $\alpha$ CD	$4.96 \pm 0.23$	$18.68 \pm 1.69\%$	1.01
$^{68}\text{Ga}$ -cyclosporin A- $\alpha$ CD	$4.97 \pm 0.08$	$19.19 \pm 1.35\%$	1.04

<sup>a</sup> ratio of RCP of the sample in presence of drug molecule/the absence of drug molecule

## Chapter V

### Conclusion

CDs are commonly used as pharmaceutical excipients, which well-known for their ability to form inclusion complexes with poorly water-soluble drugs. They offer versatile benefits in many industries, such as food, textiles and packaging, cosmetics and personal care, etc. Recently, CDs have been promising for the application of medical imaging, particularly in the development and formulation of radiopharmaceuticals for nuclear medicine imaging. In this study, we focus exclusively on the complex formation of Ga-68 and  $\alpha$ CD. To the best of our knowledge, we believed we were pioneering to achieve the successful radiosynthesis of  $^{68}\text{Ga}$ - $\alpha$ CD without an additional chelator molecule by direct radiolabeling of Ga-68 with  $\alpha$ CD. The results obtained from the MS demonstrated that  $^{68}\text{Ga}$ - $\alpha$ CD was formed with the stoichiometry ratio of 1:1 complex of  $^{68}\text{Zn}$ - $\alpha$ CD. This ratio is also confirmed by an *in silico* computational study, which also determined the binding site of Ga-68 at either the primary or secondary rim of  $\alpha$ CD. Initially, the RCP of  $^{68}\text{Ga}$ - $\alpha$ CD is very low. The RCP is increased when using the appropriate radiostabilizer and optimized process. In our present study, it suggested that using sodium ascorbate as a radiostabilizer, the concentration of 1 mg/ml  $\alpha$ CD and the C-18 cartridge for purification were the optimal parameters for radiolabeling  $^{68}\text{Ga}$ - $\alpha$ CD. Incorporating drugs either miconazole or cyclosporin A in  $\alpha$ CD solutions, forming drug/ $\alpha$ CD inclusion complex before subjected to radiolabeling, did not interfere the binding affinity between Ga-68 and  $\alpha$ CD. Consequently,  $^{68}\text{Ga}$ - $\alpha$ CD can be used for drug-load for radiopharmaceutical applications. Our findings present the simply radiosynthesis process and obtain the promising novel synthesized  $^{68}\text{Ga}$ - $\alpha$ CD used in the field of medical imaging. However, our novel radiopharmaceutical is currently not ready for clinical use. It was noted that further improving the optimization of synthesized  $^{68}\text{Ga}$ - $\alpha$ CD is required to obtain the higher RCP of  $^{68}\text{Ga}$ - $\alpha$ CD together with lower free Ga-68. These enhancements are essential for the appropriate utilization of this novel radiopharmaceuticals in a clinical setting. Additionally, larger CDs i.e.,  $\beta$ CD,  $\gamma$ CD as ligands are also interested in CD-based Ga-68 radiosynthesis.

จุฬาลงกรณ์มหาวิทยาลัย  
**CHULALONGKORN UNIVERSITY**

## VITA

**NAME** Sirapop Sriaumpai

**DATE OF BIRTH** 9 October 1997

**PLACE OF BIRTH** Bangkok, Thailand

**INSTITUTIONS ATTENDED** Chulalongkorn university

**HOME ADDRESS** 157, soi 22, chaloem phra kiat rama 9 road, Nong Bon sub-district, Prawet district, Bangkok, Thailand, 10250.

**AWARD RECEIVED** Outstanding Poster Presentation in The 23rd International Conference of Public Health Sciences "Sustainable Public Health : Innovations for Global Impact"

จุฬาลงกรณ์มหาวิทยาลัย  
CHULALONGKORN UNIVERSITY
