KEYWORD:

Benjamaporn Tudkesorn : Selective Oxidation of H₂S in Biogas to Sulfur on V₂O₅ Catalyst Dispersed on CeO₂-MO₂ (M = Ti, Si, Zr) Mixed Oxides. Advisor: Prof. JOONGJAI PANPRANOT, Ph.D.

In this research, the characteristics and catalytic performances of V₂O₅ catalysts supported on mixed oxides CeO₂-MO₂ (M = Ti, Si, Zr) as compared to the commercial CeO₂ supported ones were studied in the selective catalytic oxidation of H₂S in biogas to sulfur at 130°C. The mixed-oxide supports were prepared by co-precipitation method with 3 wt.% vanadium loading by wet impregnation method. From the XRD and Raman spectroscopy results, all the catalysts exhibited high dispersion of V₂O₅ on the supports with the 1:1 molar ratio CeO₂-SiO₂ mixed oxide showed the highest conversion of H₂S at 73% and low selectivity of SO₂ at 19 ppm. From the O₂-TPD results, the strong interaction between V₂O₅ and support produced more oxygen vacancies and as a consequence, the V₂O₅/CeO₂-SiO₂ exhibited low temperature desorption peak of chemically adsorbed oxygen suggesting a rapid restoration of catalyst from V⁴⁺ to V⁵⁺ state, which was directly related to the limiting step of the selective oxidation of H₂S. As a consequence, the catalyst activity could be enhanced.

ACKNOWLEDGEMENTS

First, I really appreciate to express my sincere to my advisor Prof. Dr. Joongjai Panpranot for suggestions, guidance and encouragement that are useful to support me until my thesis completed. I would be grateful to Dr. Akawat Sririsuk as the chairman, Assistant Professor Dr. Palang Bumroongsakulsawat and Assistant Professor Dr. Soipatta Soisuwan as the committee for their valuable comments and suggestion on my thesis.

In addition, I am grateful to Dr. Boontida Phongthawornsakun for assistance to use the apparatus in the laboratory and teach anything useful in my thesis. Moreover, I am grateful to the scientists, my seniors and my friends for all support.

Finally, I gratefully acknowledge financial supports from the Thailand Research Fund and the Malaysia-Thailand Joint Authority (MTJA).

CHAPTER I

INTRODUCTION

1.1 Introduction

Biofuel or biogas is an eco-friendly for energy production. It is naturally the decompose of organic, food and animal waste, in an anaerobic environment and is now becoming an important source of green and clean energy [1]. Biogas contains mainly two compounds are methane (CH₄) and carbon dioxide (CO₂) in different percentages depending on the source of decompose. There are 0-1% composition of other components such as hydrogen sulfide (H₂S), hydrogen (H₂), nitrogen (N₂), oxygen (O₂), carbon monoxide (CO) and ammonia (NH₃) [2, 3].

The presence of H₂S strongly affects the use of biogas in equipment directly and indirectly by the means of contraction between H₂S and moisture which results in sulfuric acid. For the carbon steel and alloyed steel, the corrosion rate by H₂S is around 0.1-1 mm/year to the wall. In case of combination of H₂S and moisture, the corrosion rate by sulfuric acid was 1-3 mm/year to the wall of carbon steels. The corrosive tendency effect increases when temperature increases, at temperature of 100 °C it exceeds 10 mm/year. Therefore, In order to protect the equipment, H₂S must be removed from biogas before entering to the process [4].

The most popular conversion method used for removal of H₂S is the Claus process which involves burning of the H₂S in air at high temperature of 980-1540 °C and high pressure of 70 kPa. The selective H₂S catalytic oxidation is an interesting alternative method for H₂S removal because it operates at low temperature and low pressure [5-7].

Total oxidation of H₂S is following reaction (1) : [8]

Selective oxidation of H₂S to sulfur element is following reaction (2)-(5): [9]

Vanadium-based catalysts have been reported to be active for selective catalytic oxidation of hydrogen sulfide (H_2S) to sulfur [10-13]. A series of $\text{CeO}_2\text{-MO}_2$ ($\text{M} = \text{Ti}^{4+}$, Si^{4+} and Zr^{4+}) supported vanadium catalyst were investigated and $\text{V}_2\text{O}_5/\text{CeO}_2$ showed better performance compared with TiO_2 and CuFeO_4 [8]. In this experiment, CeO_2 -based mixed metal oxide were prepared and employed as the supports for preparation of supported V_2O_5 catalysts in the selective oxidation of H_2S to sulfur compound.

In this research, we aim to study the characteristics and catalytic activity of V_2O_5 dispersed on pure CeO_2 and $\text{CeO}_2\text{-MO}_2$ mixed oxide supports prepared with different molar ratios between CeO_2 and MO_2 in the selective oxidation of H_2S to sulfur element. This research contains three parts of studies: first, preparation the mixed-metal oxide supports, $\text{CeO}_2\text{-TiO}_2$, $\text{CeO}_2\text{-SiO}_2$ and $\text{CeO}_2\text{-ZrO}_2$ using co-precipitation method and preparation of 3 wt.% of V_2O_5 supported on $\text{CeO}_2\text{-MO}_2$ using impregnation method: second, the properties and characteristics of catalysts analyzed by X-ray diffraction (XRD), Raman spectroscopy, N_2 -physisorption, Inductively coupled plasma-optical emission spectrometry (ICP-OES), Scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX), Fourier transforms infrared spectroscopy (FT-IR), X-ray photoelectron spectroscopy (XPS) and Oxygen-Temperature programmed desorption (O_2 -TPD). And the last part is the catalytic activity test were carried out in H_2S oxidation at 130°C and atmospheric pressure.

1.2 Objectives of the Research

To study the characteristics and catalytic performances of CeO_2 and $\text{CeO}_2\text{-MO}_2$ ($\text{M} = \text{Ti}, \text{Si}, \text{Zr}$) supported V_2O_5 in the selective catalytic oxidation of H_2S .

1.3 Scope of the Research

1.3.1 To study the characteristics and catalytic performances of CeO_2 and CeO_2 - MO_2 ($M = \text{Ti, Si, Zr}$) supported V_2O_5 in the selective catalytic oxidation of H_2S

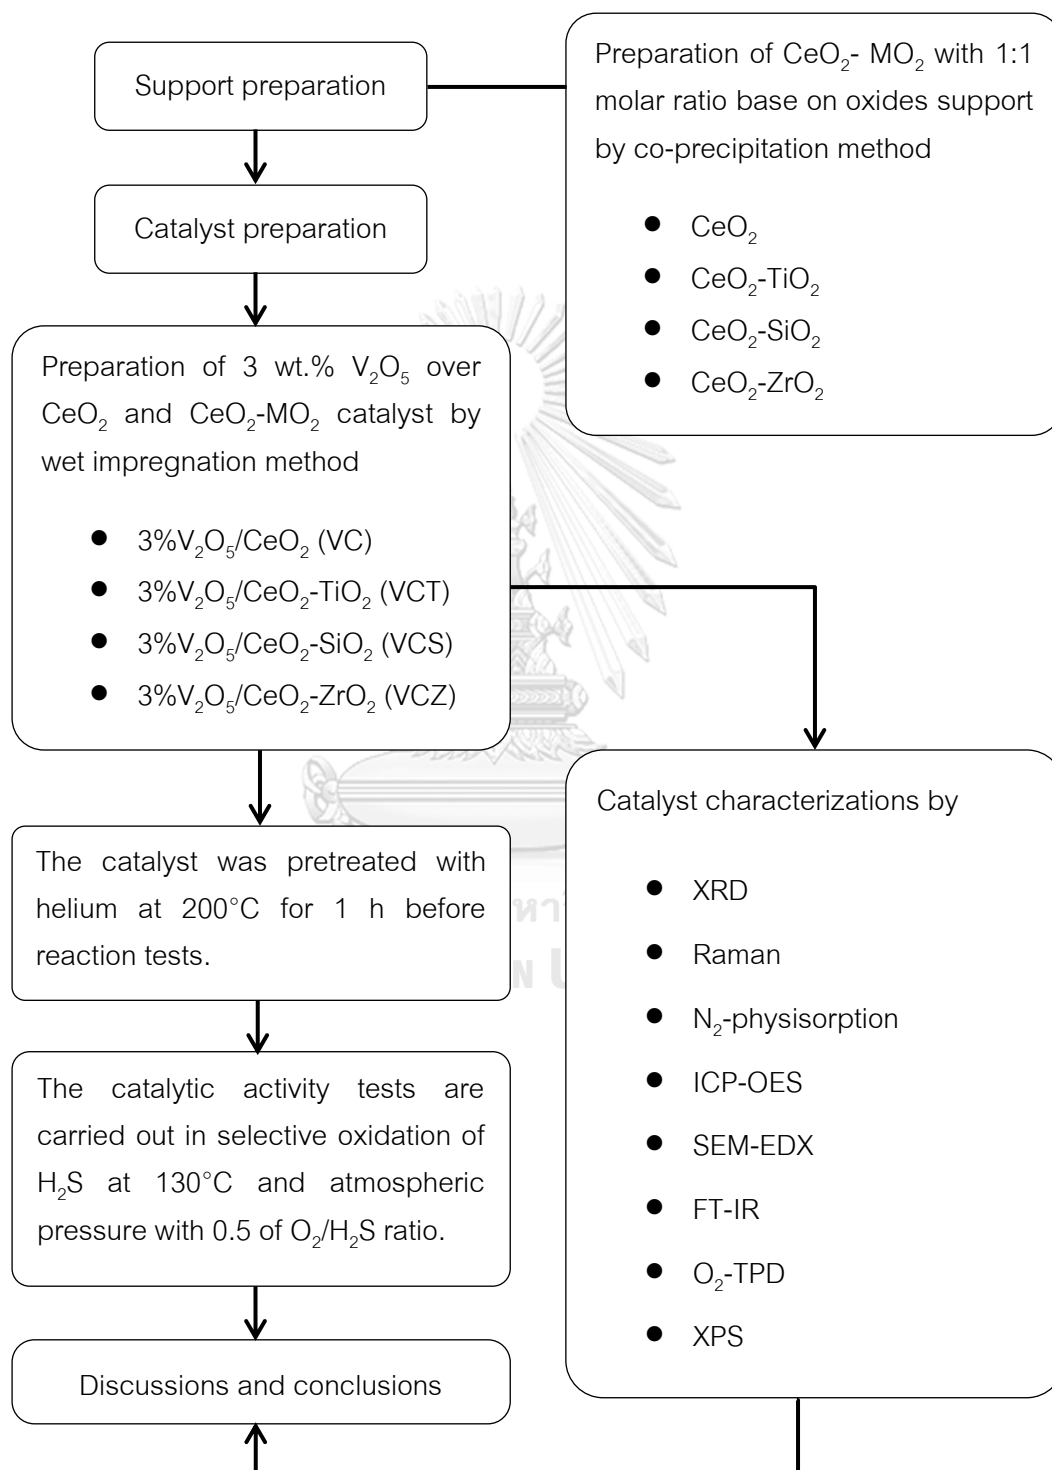

- 1) Preparation of CeO_2 - MO_2 with 1:1 molar ratio ($M = \text{Ti, Si, Zr}$) support by coprecipitation method and calcined at 500°C for 5 h in air with $10^\circ\text{C}/\text{min}$ of ramp rate on temperature.
- 2) Preparation of 3 wt.% V_2O_5 over CeO_2 and CeO_2 - MO_2 ($M = \text{Ti, Si, Zr}$) catalyst by wet impregnation method and calcined at 500°C for 5 h in air with $10^\circ\text{C}/\text{min}$ of ramp rate on temperature.
- 3) The catalysts were pretreated with helium at 200°C for 1 h before reaction tests.
- 4) The catalytic activity tests were carried out in selective oxidation of H_2S at 130°C and atmospheric pressure with 0.5 of $\text{O}_2/\text{H}_2\text{S}$ ratio.
- 5) Characterization of the prepared catalysts by various method following
 - 5.1) X-ray diffraction (XRD)
 - 5.2) Raman spectroscopy
 - 5.3) N_2 -physisorption
 - 5.4) Inductively coupled plasma-optical emission spectrometry (ICP-OES)
 - 5.5) Scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX)
 - 5.6) Fourier transforms infrared spectroscopy (FT-IR)
 - 5.7) Oxygen-Temperature programmed desorption (O_2 -TPD)
 - 5.8) X-ray photoelectron spectroscopy (XPS)

1.3.2 The best catalyst from above study was selected to study the effect of mixing molar ratio between CeO_2 and MO_2 support on catalytic performance for selective catalytic oxidation of H_2S .

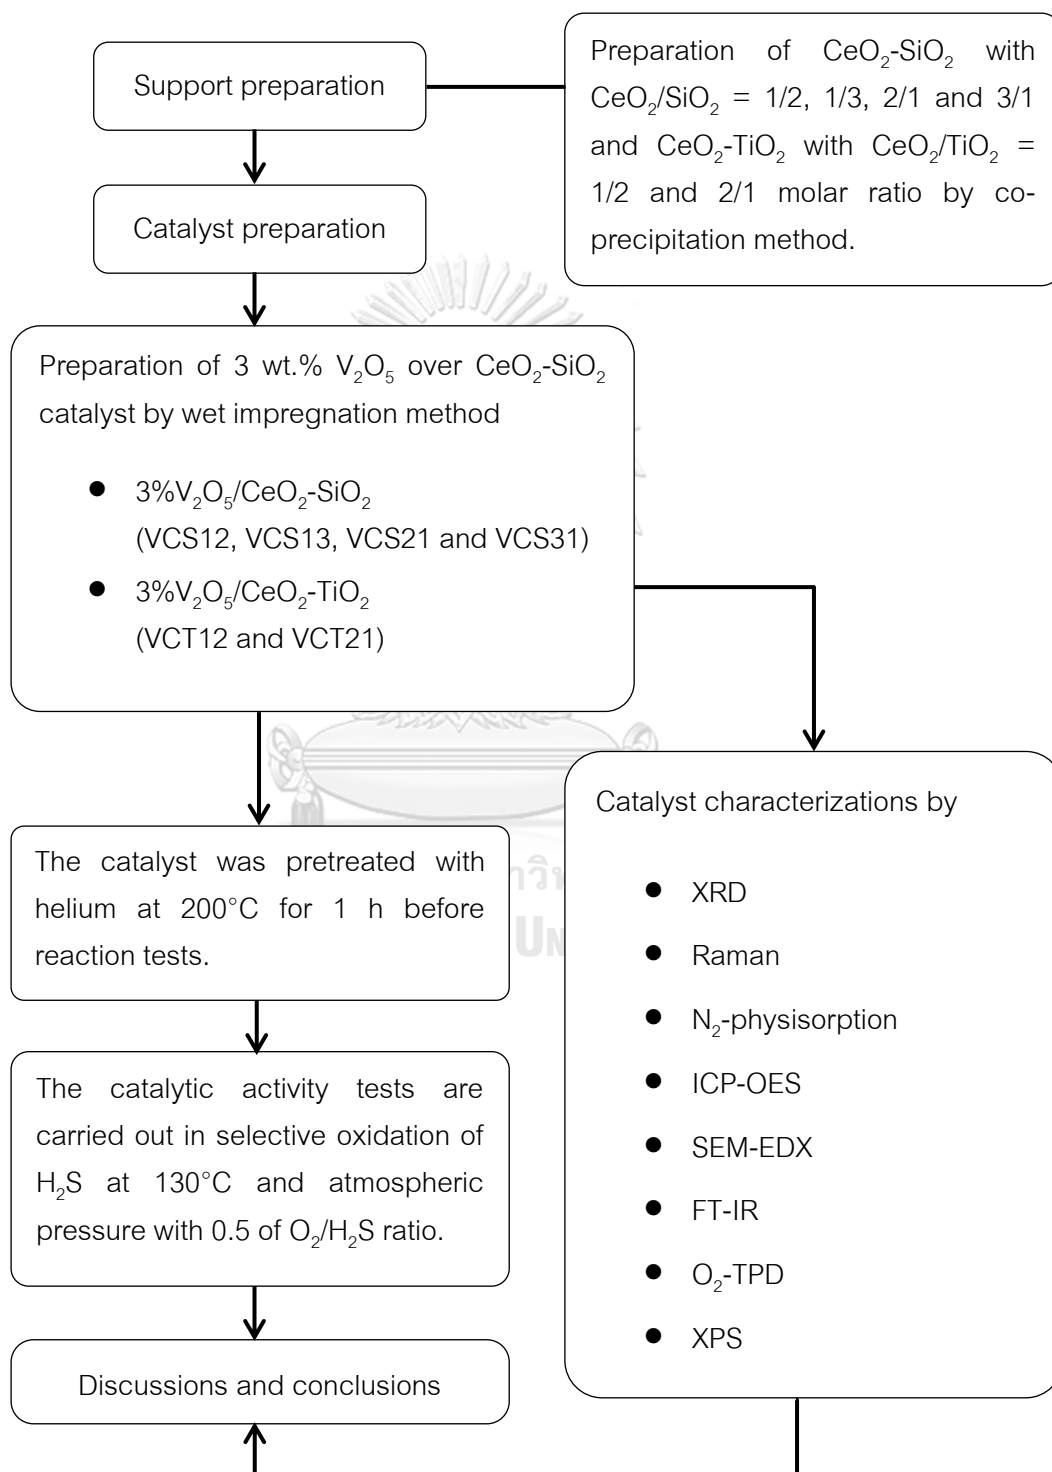

- 1) Preparation of CeO_2 - MO_2 with desired molar ratio support by co-precipitation method and calcined at 500°C for 5 h in air with $10^\circ\text{C}/\text{min}$ of ramp rate on temperature.
- 2) Preparation of 3 wt.% V_2O_5 over mixed oxide support catalyst by wet impregnation method and calcined at 500°C for 5 h in air with $10^\circ\text{C}/\text{min}$ of ramp rate on temperature.
- 3) The catalysts were pretreated with helium at 200°C for 1 h before reaction tests.
- 4) The catalytic activity tests are carried out in selective oxidation of H_2S at 130°C and atmospheric pressure with 0.5 of $\text{O}_2/\text{H}_2\text{S}$ ratio.
- 5) Characterization of the prepared catalysts by various method following
 - 5.1) X-ray diffraction (XRD)
 - 5.2) Raman spectroscopy
 - 5.3) N_2 -physisorption
 - 5.4) Inductively coupled plasma-optical emission spectrometry (ICP-OES)
 - 5.5) Scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX)
 - 5.6) Fourier transforms infrared spectroscopy (FT-IR)
 - 5.7) Oxygen-Temperature programmed desorption (O_2 -TPD)
 - 5.8) X-ray photoelectron spectroscopy (XPS)

1.4 Research Methodology

1.4.1 To study the characteristic and catalytic performance of CeO_2 and CeO_2 - MO_2 ($\text{M} = \text{Ti}, \text{Si}, \text{Zr}$) supported V_2O_5 in the selective catalytic oxidation of H_2S

1.4.2 The best catalyst from above study was selected to study the effect of mixing molar ratio between CeO_2 and MO_2 (SiO_2 and TiO_2) support on catalytic performance for selective catalytic oxidation of H_2S .

CHAPTER II

BACKGROUND AND LITERATURE REVIEW

2.1 Biogas

Biofuel or biogas is an eco-friendly for energy production. It is naturally decomposition in decompose of organic, food and animal waste, in an anaerobic environment become too important source of green and clean energy, yielding 5.5-7 kWh.m⁻³. The energy directly depends on methane content [1, 14]. Biogas contains mainly two compounds are methane (CH₄) and carbon dioxide (CO₂) in difference percentage depend on source of decompose. There are 0-1% composition of each other components such as hydrogen sulfide (H₂S), hydrogen (H₂), Nitrogen (N₂), Oxygen (O₂), carbon monoxide (CO) and ammonia (NH₃) [2].

Table 1 Typical composition (%) of biogas [2].

Component	Agricultural waste	Landfills	Industrial waste
Methane (CH ₄)	50-80	50-80	50-70
Carbon dioxide (CO ₂)	30-50	20-50	30-50
Hydrogen sulfide (H ₂ S)	0.70	0.10	0.80
Hydrogen (H ₂)	0-2	0-5	0-2
Nitrogen (N ₂)	0-1	0-3	0-1
Oxygen (O ₂)	0-1	0-1	0-1
Carbon monoxide (CO)	0-1	0-1	0-1
Ammonia (NH ₃)	Trace	Trace	Trace

2.2 Hydrogen sulfide (H₂S)

The extremely hazardous hydrogen sulfide (H₂S) gas is colorless and flammable with a strongly rotten egg smell although the concentration of H₂S is very low in air. H₂S occurs naturally in petroleum crude oil, natural gas, biomass decomposition and hot spring [15]. However, is available in the processing industry such as refinery industry, heavy and metal industry, pulp and paper industry, chemical industry and public utilities i.e. bacteriological composing of west and dewatering of sewage sludge [16].

Health effects of H₂S are both irritation, block sense of smell and interrupt cells from receiving oxygen. The toxic limitation value that immediately dangerous to life and health is 100 ppm of H₂S concentration [16].

Table 2 Specifications of H₂S [16].

Synonyms	Hydrogen sulfide Hydrosulfuric acid Sulfane Dihydrogen monosulfide
Molecular Formula	H ₂ S
Molecular weight	34.08 g/mol
Density	0.002 g/mL (at 68 °F / 20 °C)
Ignition temperature	518 °F / 270 °C
Melting point	-122.08 °F / -85.6 °C
Boiling point	-76.36 °F / -60.2 °C
UEL	45.5 Vol.%
LEL	4.3 Vol.%
Hazard symbols	

The effect of H₂S on the equipment directly and indirectly by the means of contraction between H₂S and moisture result to sulfuric acid. For the carbon steel and alloyed steel, the corrosion rate by H₂S affect 0.1-1 mm/year to the wall. In the case of combination of H₂S and moisture, the corrosion rate by sulfuric acid affect 1-3 mm/year to the wall of carbon steels. The corrosive tendency effect increases when temperature increases, at temperature of 100 °C it exceeds 10 mm/year. Therefore, In order to protect the equipment, H₂S must be removed from biogas before entering to the process [4].

The most popular conversion method used to remove H_2S is the Claus process which involves hydrogen sulfide burning in air at high temperature of $980\text{--}1540^\circ\text{C}$ and high pressure of 70 kPa. The other alternative is selective H_2S catalytic oxidation, was operated at low temperature and low pressure [7].

2.3 Elimination of hydrogen sulfide [7, 17]

Claus process is the most common used to recover the hydrogen sulfide and converted to sulfur element. Claus process also consist of multistage following:

1) Thermal oxidation

One-third of hydrogen sulfide (H_2S) is burning with air to generate sulfur dioxide (SO_2) at temperature of $980\text{--}1540^\circ\text{C}$ and higher pressure of 70 kPa.

2) Catalytic reaction

Two-third remaining unconverted of hydrogen sulfide (H_2S) reacts with sulfur dioxide to produce sulfur element through the subsequent catalytic reaction at temperature of $200\text{--}315^\circ\text{C}$. From the limitation in chemical equilibrium reaction, 3-5% of H_2S cannot converted to sulfur element. So, it is necessary to treat the residual gas of the Claus process by another techniques such as adsorption wet catalytic reaction and catalytic reaction.

Figure 1 Claus sulfur recovery unit diagram [18].

The importance developed processes to treat the residual gas from Claus process are Mobil direct oxidation process (MODOP) and Super Claus process. The principles of two processes are based on the irreversible selective oxidation of H_2S [19].

Total oxidation of hydrogen sulfide is following reaction (8): [8]

Selective oxidation of hydrogen sulfide to sulfur element is responded following reaction (9)-(12): [9]

2.4 Vanadium pentoxide

Vanadium pentoxide (V_2O_5) appears as a yellow to rust-brown crystalline powder and slightly soluble in water. Vanadium pentoxide is popularly used in oxidation catalyst both homogeneous and heterogeneous processes for many industries such as the sulfuric acid production from sulfur dioxide, adipic from cyclohexanol and acetaldehyde from alcohol. The preparation of vanadium pentoxide also involves the ammonium metavanadate decomposition at temperature of 500-550 °C [20, 21].

Figure 2 Vanadium pentoxide [22]

Table 3 Physical/chemical properties of vanadium pentoxide [23]

Synonyms	Vanadium (V) oxide Divanadium pentoxide
Molecular Formula	V_2O_5
Molecular weight	181.88 g/mol
Density	3.357 g/cm^3
Flash point	Non-flammable
Melting point	690°C
Boiling point	$1,750^\circ \text{C}$ (decompose)
Solubility in water	0.8 g/L at 20°C
Hazard symbols	

Davydov et al. (2003) [10] Study the catalytic activity of 12 metal oxides (MgO , TiO_2 , ZrO_2 , V_2O_5 , Mn_2O_3 , Cr_2O_3 , Fe_2O_3 , CuO , CoO , Al_2O_3 , Sb_6O_{13} and Bi_2O_3) in selective oxidation of H_2S by molecular of oxygen to propose for sulfur selective production. V_2O_5 is the most active catalyst for the selective catalytic oxidation of H_2S to give high conversion of H_2S while BiO_3 , Fe_2O_3 and CuO mainly carried out the SO_2 formation in complete oxidation of H_2S reaction.

Li et al (1996) [9] Study the catalytic activity of hydrogen sulfide selective oxidation over single oxide, the result shows that vanadium oxide had to be the best performance in H_2S conversion and sulfur selectivity. The catalytic activity decreased in the following iron oxide, bismuth oxide, molybdenum oxide and magnesium oxide respectively. In case of vanadium-based mixed oxide catalyst studied, consist of vanadium-molybdenum ($V/Mo = 1/0, 5/1, 2/1, 1/1, 2/7$ and $0/1$), vanadium-bismuth ($V/Bi = 1/0, 2/1, 1/1, 1/2$ and $0/1$) and vanadium-magnesium ($V/Mg = 1/0, 3/1, 1/1, 1/3$ and $0/1$). the addition of Mo, Bi and Mg significantly improve the catalytic performance due to exhibits strong synergistic behavior.

Kim et al (2006) [24] The selective oxidation of hydrogen sulfide containing excess water and ammonia were studied over the V_2O_5/TiO_2 aerogel catalyst. The aerogel catalyst with 2 wt.% of vanadium oxide showed the highest surface area compared with higher content of vanadium (5 wt.% and 10 wt.%). The comparison between V_2O_5/TiO_2 aerogel and xerogel catalyst, aerogel catalyst exhibited on higher conversion of H_2S without SO_2 formation.

Soriano et al (2015) [5] V_2O_5 supported on porous clay heterostructure (PCH) catalysts were studied for the partial oxidation of H_2S . The catalyst with higher V_2O_5 content are more active, a higher of H_2S conversion and SO_2 selectivity, and resistance to the deactivation.

Soriano et al (2009) [25] V_2O_5 supported on mesoporous zirconium phosphate (MZP) catalyst were studied for the selective oxidation of H_2S . The catalytic activity and stability increasing with the V-loading and sulfur deposit on the catalyst is favored in catalyst with low V-loading.

Pongthawornsakun et al (2018) [12] TiO_2 supported vanadium oxide were investigated at $130^\circ C$ for selective oxidation of H_2S . V_2O_5/TiO_2 (anatase) exhibited the best catalyst performance with 80% conversion of H_2S and low selectivity of SO_2 (<7 ppm). The highly dispersed vanadium oxide on the support result to partially reduced V-Ti species influenced the redox capability of V^{5+}/V^{4+} , directly affect to the limiting step of reaction.

2.5 Cerium (IV) oxide

Cerium (IV) oxide (CeO_2) appears as a yellow to white powder. CeO_2 is insoluble in water and moderately soluble in strong mineral acids. Ceria was used as a catalyst in automotive application and co-catalyst in many reaction such as Fischer-Tropsch reaction, selective oxidation and steam reforming of ethanol into carbondioxide and hydrogen. The structure of ceria is fluorite, oxygen atom are all in a plane which allows for rapid diffusion of the oxygen vacancies [26].

Figure 3 Cerium oxide [27]

Table 4 Physical/chemical properties of cerium oxide [26]

Synonyms	Cerium dioxide Ceria
Molecular Formula	CeO ₂
Molecular weight	172.11 g/mol
Density	7.65 g/cm ³
Melting point	2,500 °C
Boiling point	3,500 °C
Solubility in water	Insoluble
Hazard symbols	

Barba et al (2013) [8] To compare the activity for selective catalytic H₂S oxidation, different vanadium (V₂O₅) based supported catalyst including TiO₂, CeO₂ and CuFe₂O₄ were studied. The surface area of the supported was decreased after V₂O₅ doped because V₂O₅ could be clogging in the pore of support but V₂O₅/CuFe₂O₄ wasn't observed the difference of surface area after V₂O₅ doped due to the initial specific surface area of CuFe₂O₄ is very low. At the reaction temperature of 250 °C, the result has shown a higher conversion of H₂S and low selectivity of SO₂ at 3% on CeO₂ supported V₂O₅. From studied the effect of temperature on the reaction, it was found that the conversion of H₂S increase and selectivity of SO₂ decrease when reaction temperature increased.

Palma et al (2014) [11] To study the catalytic activity for selective catalytic H₂S oxidation of CeO₂ supported vanadium (V₂O₅) catalyst in different loading of V₂O₅. 2.55-20 wt.% loading of V₂O₅ on the support were characterized, the result showed increasing of vanadium content could lead to blocking and clogging in the pores of support result to decrease the surface area of catalyst. For 20 wt.% loading of V₂O₅, cerium vanadate (CeVO₄) can be observed at XRD peak of 2 θ ~ 24°, 32.4° and 33.1° due to the reaction between CeO₂ and V₂O₅ following:

After catalytic activity test of 20 wt.% V₂O₅/CeO₂, the catalyst was a good activity with 99% of sulfur selectivity and 98.7% of H₂S conversion at 150 °C which very close to the calculation of thermodynamic equilibrium.

Zang et al (2013) [13] A series of vanadium supported on ceria doped with Lamponite clay catalyst was studied the structural and activity for selective oxidation of H₂S. V₂O₅/CeO₂-Lap is a mesoporous structure with high surface area. The emperature programed desorption technique was used to characterize the ability to adsorb and desorb O₂ of catalyst. The peak observed at 120 °C attributed to chemically adsorbed oxygen. The peak at 450 °C represented to desorption of oxygen molecule on the oxygen vacancies. For the 5% V₂O₅/CeO₂-Lap exhibits the largest peak, indicating that it is the largest of oxygen vacancies amount which agreeable with the result from the activity test. The maximum conversion of H₂S is 98% and yield of sulfur is 98% at 180 °C. In order to study the catalyst deactivated after reaction time for 7 h, catalyst as purge with the N₂ at 300 °C and then fed with 2% O₂. The experiments are shown the existence of Ce³⁺ could be resistant to the deactivation of catalyst.

Yasyerli et al (2006) [28] Ce-V mixed oxides have studied the activity for selective oxidation of H₂S to sulfur, Ce-V mixed oxide atomic ratio of one (Ce/V = 2/2) showed 100% H₂S conversion when O₂/H₂S feed ratios of 0.5 used at 250 °C. The selectivity of sulfur decreased with O₂/H₂S ratio increased to over the stoichiometric value.

2.6 Mixed metal oxide

Reddy et al (2004) [29] To investigate structural characteristics of a series of V_2O_5/CeO_2-MO_2 ($M = Si^{4+}$, Ti^{4+} and Zr^{4+}) with 1:1 molar ratio catalyst. The highest surface area found on CeO_2-SiO_2 support.

For the CeO_2-SiO_2 , the result from XRD indicating that SiO_2 is an amorphous due to the peak of SiO_2 are absent. Calcination of catalyst at $500^\circ C$, $600^\circ C$ and $800^\circ C$ gave a good dispersion of V_2O_5 , formation of $CeVO_4$ and formation of $Ce_{9.33}(SiO_4)_6O_2$ phase between CeO_2 and SiO_2 respectively. For the CeO_2-TiO_2 , the result from XRD indicating that TiO_2 is an anatase phase with a few formation of $CeVO_4$ at calcination of $500^\circ C$. Calcination of catalyst at $800^\circ C$ and $1250^\circ C$, TiO_2 rutile phase and Ce-Ti oxides (Ce_2TiO_5 , $Ce_2Ti_2O_7$ and $Ce_4Ti_9O_{24}$) could be found respectively. For the CeO_2-ZrO_2 , the result from XRD showed CeO_2-ZrO_2 is a cubic fluorite-type with composition $Ce_{0.75}Zr_{0.25}O_2$ when calcined at $500^\circ C$. Calcination of catalyst at $500^\circ C$ and $800^\circ C$, $Ce_{0.4}Zr_{0.6}O_2$ and tetragonal phase of $Ce_{0.16}Zr_{0.84}O_2$ are visible respectively. The RS results, show the oxygen vacancies/ Ce^{3+} presence in different proportion in all sample.

Shin et al (2001) [17] VO_x/SiO_2 catalysts were investigated using a packed bed reactor for selective oxidation of H_2S . The conversion of H_2S is very high values ($>90\%$) for V_2O_5/SiO_2 at $270-350^\circ C$.

Reddy et al (2002) [30] Characterization of V_2O_5/CeO_2-SiO_2 calcined at $500-800^\circ C$. The catalyst is a very high specific surface area and the surface of SiO_2 was covered by CeO_2 . At high calcination temperature, the XRD shown $CeVO_4$ peak due to the reaction between V_2O_5 and CeO_2 . V^{5+} has been found at the surface when calcination temperature increased.

Kang et al (2015) [31] CeO_2-TiO_2 were studied for catalytic oxidation of H_2S in a vary atom ratio of Ce/Ti are 1/1, 1/3, 1/5 and 3/1. The surface area of mixed-oxide CeO_2-TiO_2 is higher than pure cerium oxide. The highest surface area was investigated when atom ration of Ce/Ti is 1/3, decreasing of surface area occur when Ce content increased. Catalysts with Ce/Ti = 1/3 and 1/5 exhibited the highest conversion of H_2S because the uniform dispersion of metal oxides.

Table 5 Summary the research of the catalytic oxidation of H₂S to elemental sulfur.

Researcher	Study	Catalyst	Reaction condition	Result
Davydov et al. (2003) [10]	Catalytic activity of metal oxide in H ₂ S oxidation	MgO, CaO, La ₂ O ₃ , TiO ₂ , ZrO ₂ , V ₂ O ₅ , Cr ₂ O ₃ , MoO ₃ , Mn ₂ O ₃ , Fe ₂ O ₃ , CoO, NiO, CuO, ZnO, Al ₂ O ₃ , Ga ₂ O ₃ , In ₂ O ₃ , SiO ₂ , SnO ₂ , Sb ₆ O ₁₃ and Bi ₂ O ₃	Feed concentration is 0.5 vol.% of H ₂ S and 0.25 vol.% of O ₂ T = 250 °C	V ₂ O ₅ is the best performance for selective oxidation of H ₂ S to sulfur both total and selective oxidation of H ₂ S
Li et al (1996) [9]	Catalytic activity of vanadium-based mixed-oxide in selective oxidation of H ₂ S	Iron oxide Vanadium oxide Bismuth oxide Magnesium oxide Molybdenum oxide V/Mo V/Bi V/Mg	Molar ratio of H ₂ S:O ₂ = 1/5 T = 200 - 220 °C	Vanadium oxide is the best performance and Mo, Bi and Mg significantly improve the catalytic performance more than pure vanadium oxide at any temperature

Kim et al (2006) [24]	Performance of a series of V_2O_5/TiO_2 aerogel were prepared by sol-gel method	2% V_2O_5/TiO_2 5% V_2O_5/TiO_2 10% V_2O_5/TiO_2 (aerogel) 5% V_2O_5/TiO_2 (xerogel) 5% V_2O_5/TiO_2 (impregnated)	Feed mixture composed of $H_2S/O_2 = 5.0/2.5$ $T = 220-260^\circ C$	5% V_2O_5/TiO_2 aerogel catalyst exhibited on higher conversion of H_2S without SO_2 formation
Soriano et al (2015) [5]	Catalytic activity of V_2O_5 on porous clay heterostructure (PCH) in partial oxidation of H_2S	2% V_2O_5/PCH 4% V_2O_5/PCH 8% V_2O_5/PCH 12% V_2O_5/PCH 16% V_2O_5/PCH	Feed mixture composed of $H_2S/air = 1.2/5.0$ $T = 180^\circ C$	The catalyst with higher V_2O_5 content are more active with higher of H_2S conversion and SO_2
Soriano et al (2009) [25]	Catalytic activity of V_2O_5 on mesoporous zirconium phosphate heterostructure (MZP) in partial oxidation of H_2S	MZP 2% V_2O_5/MZP 4% V_2O_5/MZP 8% V_2O_5/MZP 12% V_2O_5/MZP 16% V_2O_5/MZP V_2O_5	Feed mixture composed of $H_2S/air = 1.2/5.0$ $T = 180 - 260^\circ C$	The catalytic activity and stability increasing with the V-loading and sulfur deposit on the catalyst is favored in catalyst with low V-loading.

Pongthawornsakun et al (2018) [12]	Activity of TiO ₂ supported vanadium oxide for selective oxidation of H ₂ S	V ₂ O ₅ /anatase-43 V ₂ O ₅ /anatase-21 V ₂ O ₅ /solvo V ₂ O ₅ /P25 V ₂ O ₅ /rutile	Feed mixture composed of 300 ppm of H ₂ S and 150 ppm of O ₂ T = 130 °C	V ₂ O ₅ /anatase-21 exhibited the best catalyst performance with 80% conversion of H ₂ S and low selectivity of SO ₂ (<7 ppm)
Barba et al (2013) [8]	Catalytic activity of vanadium-based support on mixed oxide in partial oxidation of H ₂ S	CeO ₂ TiO ₂ CuFe ₂ O ₄ V ₂ O ₅ / CeO ₂ V ₂ O ₅ / TiO ₂ V ₂ O ₅ / CuFe ₂ O ₄	Feeding 1000 ppm of H ₂ S, 500 ppm of O ₂ T = 50 – 250 °C	V ₂ O ₅ / CeO ₂ exhibited the highest conversion of H ₂ S and low selectivity of SO ₂ . The selectivity of SO ₂ decrease with reaction temperature increased.
Palma et al (2014) [11]	Catalytic activity for selective oxidation of H ₂ S on CeO ₂ supported vanadium (V ₂ O ₅) catalyst at varies V ₂ O ₅ load	2.55% V ₂ O ₅ / CeO ₂ 5% V ₂ O ₅ / CeO ₂ 8% V ₂ O ₅ / CeO ₂ 10% V ₂ O ₅ / CeO ₂ 20% V ₂ O ₅ / CeO ₂	Feeding 200 ppm of H ₂ S, 100 ppm of O ₂ T = 150 – 250 °C	20 wt.% V ₂ O ₅ /CeO ₂ , catalyst was a good activity with 99% of sulfur selectivity and 98.7% of H ₂ S conversion at 150 °C

Zang et al (2013) [13]	The structural and activity of a series of vanadium supported on ceria doped with Lamponite clay catalyst for selective oxidation of H ₂ S	3% V ₂ O ₅ /Ce-Lap 5% V ₂ O ₅ /Ce-Lap 8% V ₂ O ₅ /Ce-Lap	Feeding 5000 ppm of H ₂ S, 2500 ppm of O ₂ T = 120 – 220 °C	5% V ₂ O ₅ /Ce-Lap catalyst presented the best catalytic activity and could be resistance the deactivation of catalyst.
Yasyerli et al (2006) [28]	Catalytic activity of Ce-V mixed oxide in partial oxidation of H ₂ S	CeO ₂ Ce3V1 Ce2V2 Ce1V3	Molar ratio of H ₂ S/O ₂ = 0.5 T = 200 - 300 °C	Ce-V mixed oxide atomic ratio of one (Ce/V = 2/2) showed 100% H ₂ S conversion when O ₂ /H ₂ S feed ratios of 0.5 used at 250 °C

2.8 Catalytic Mechanism

Although the literature widely proposed the type of mechanism for the total catalytic oxidation reaction of H₂S on the vanadium catalyst as Langmuir–Hinshelwood and Rideal-type or Rideal–Eley-type mechanisms. For the selective oxidation of H₂S reaction over supported V₂O₅ catalyst, Mars-van Krevelen or so-called redox mechanism is usually established to explain the oxidized active site on the catalyst surface oxidizes the reactant and regenerated back to the original (re-oxidized) by the oxygen in gas phase in a stepwise mechanism [10].

A stepwise mechanism for the selective oxidation of H_2S reaction over supported V_2O_5 catalyst is shown in Figure 4. First, the reaction occurs on the active site vanadium with H_2S in gas phase. H_2S adsorbed on the active site and take oxygen atom from V_2O_5 to produce the products of sulfur element and water. H_2S was oxidized to sulfur by V^{5+} . At the same time, V^{5+} was reduced to V^{4+} then oxygen vacancies occurred. Simultaneously, oxygen in the gas phase was adsorbed on the catalyst surface, V^{4+} was re-oxidized back to the initial state by reacting with oxygen in the gas phase called re-oxidation. The catalytic activity was determined based on the redox cycle of V^{5+} [12]. Shin et al. [27] rate of re-oxidation step much slower than the reduction step by H_2S so, the re-oxidation step would be as the limiting step which affect significantly to the performance of the catalyst.

Figure 4 Proposed mechanism of H_2S selective oxidation on the supported V_2O_5 [12]

CHAPTER III

MATERIALS AND METHODS

The experiment is described in this chapter, which is divided into three parts including catalyst preparation, catalyst characterization, and H₂S oxidation reaction test.

3.1 Catalyst preparation

V₂O₅ (3 wt.%) on the CeO₂ and modified CeO₂-MO₂ mixed-oxides (M = Ti⁴⁺, Si⁴⁺ and Zr⁴⁺) support were prepared by wet impregnation.

3.1.1 Preparation of CeO₂ support

CeO₂ was prepared into two samples, The first one is commercial powder CeO₂ provide by Sigma-Aldrich and the second one was synthesized. Synthesized CeO₂ was obtained by calcination Ce(NO₃)₃·6H₂O at 500°C for 5 h in air with 10°C/min of ramp rate on temperature. The chemicals are shown in Table 6.

Table 6 The chemicals for Preparation of CeO₂-TiO₂ (1:1 molar ratio) support

Chemical	Formula	Supplier
Cerium (III) nitrate hexahydrate, 99.5%	Ce(NO ₃) ₃ ·6H ₂ O	Sigma-Aldrich
Cerium (IV) oxide, < 25 nm	CeO ₂	Sigma-Aldrich

3.1.2 Preparation of CeO₂-TiO₂ (1:1 molar ratio base on oxide) support

CeO₂-TiO₂ support was synthesized by co-precipitation method. 3.5 g of cerium (III) nitrate hexahydrate and 2.8 g titanium (IV) butoxide were dissolved in 30 ml of distilled water and 30 ml of ethanol respectively. The solution were mixed together. Ammonium hydroxide was added to the previous mixture solution until precipitation was complete at pH = 8 and stirred at 80°C on a heating plate for 1 h. The chemicals are shown in Table 7. After obtained hydroxide gels, the solution were washed with deionize water, dried at 110 °C overnight in oven and calcined at 500°C for 5 h in air with 10°C/min of ramp rate on temperature.

Table 7 The chemicals for Preparation of CeO₂-TiO₂ (1:1 molar ratio) support

Chemical	Formula	Supplier
Cerium (III) nitrate hexahydrate, 99.5%	Ce(NO ₃) ₃ ·6H ₂ O	Sigma-Aldrich
Titanium (IV) butoxide, 97%	Ti(C ₄ H ₉ O) ₄	Sigma-Aldrich
Ammonium hydroxide, 28% NH ₃ in water, 99.99%	NH ₄ OH	Sigma-Aldrich

3.1.3 Preparation of CeO₂-SiO₂ (1:1 molar ratiion base on oxide) support

CeO₂-SiO₂ support was synthesized by co-precipitation method. 4.7 g of ammonium cerium (IV) nitrate was dissolved in 30 ml of distilled water and mixed together with 1 ml of colloidal silica. Ammonium hydroxide was added to the previous mixture solution until precipitation was complete at pH = 8 and stirred at 80°C on a heating plate for 1 h. The chemicals are shown in Table 8. After obtained hydroxide gels, the solution were washed with deionize water, dried at 110 °C overnight in oven and calcined at 500°C for 5 h in air with 10°C/min of ramp rate on temperature.

Table 8 The chemicals for Preparation of CeO₂-SiO₂ (1:1 molar ratio) support

Chemical	Formula	Supplier
Ammonium cerium (IV) nitrate, > 99.99%	Ce(NH ₄) ₂ (NO ₃) ₆	Sigma-Aldrich
Colloidal silica, 40 wt.% suspension in H ₂ O		Sigma-Aldrich
Ammonium hydroxide, 28% NH ₃ in water, 99.99%	NH ₄ OH	Sigma-Aldrich

3.1.4 Preparation of CeO₂-ZrO₂ (1:1 molar ratio base on oxide) support

CeO₂-ZrO₂ support was synthesized by co-precipitation method. 3.2 g of cerium (III) nitrate hexahydrate and 1.5 g zirconium (IV) oxynitrate hydrate were dissolved in 30 ml of distilled water separately. The solution were mixed together. Ammonium hydroxide was added to the previous mixture solution until precipitation was complete at pH = 8 and stirred at 80°C on a heating plate for 1 h. The chemicals are shown in Table 9. After obtained hydroxide gels, the solution were washed with deionize water, dried at 110 °C overnight in oven and calcined at 500°C for 5 h in air with 10°C/min of ramp rate on temperature.

Table 9 The chemicals for Preparation of CeO₂-TiO₂ (1:1 molar ratio) support

Chemical	Formula	Supplier
Cerium (III) nitrate hexahydrate, 99.5%	Ce(NO ₃) ₃ ·6H ₂ O	Sigma-Aldrich
Zirconium (IV) oxynitrate hydrate, 99%	ZrO(NO ₃) ₂ ·2H ₂ O	Sigma-Aldrich
Ammonium hydroxide, 28% NH ₃ in water, 99.99%	NH ₄ OH	Sigma-Aldrich

3.1.5 Preparation of 3 wt.% V₂O₅ over CeO₂ and CeO₂-MO₂ Catalyst

3 wt.% V₂O₅ over CeO₂-MO₂ was synthesized by wet impregnation method. Ammonium metavanadate was dissolved in 1 M of oxalic acid solution and adding support into the solution. The chemicals are shown in Table 10. The solution was stirred at 80°C on a heating plate until completing in evaporating, dried at 110 °C overnight in oven and calcined at 500°C for 5 h in air with 10°C/min of ramp rate on temperature.

Table 10 The chemicals for Preparation of 3 wt.% V₂O₅ over CeO₂-MO₂ Catalyst

Chemical	Formula	Supplier
Ammonium metavanadate, 99.99%	NH ₄ VO ₃	Sigma-Aldrich
Cerium (IV) oxide, < 25 nm	CeO ₂	Sigma-Aldrich
Mixed-oxide support from 4.1.1-4.1.3	CeO ₂ -MO ₂	-

3.2 Reaction test in H₂S oxidation

Figure 5 Flow diagram of H₂S oxidation reaction system.

0.03 g of catalysts were packed into the glass fixed bed reactor which the inner diameter is 9 mm, supported the catalyst with 0.15 g of quartz wool. Before the reaction test, the catalyst was pretreat with 50 ml/min of Helium at 200 °C for 1 h. The activity test for selective oxidation of H₂S were carried out in temperature of 130 °C and atmospheric pressure for 3 h with gaseous mixture feed containing of 400 ppm of H₂S, 200 ppm of O₂, 1.3% of CH₄, 1.3% of CO₂, and 2% of N₂ balanced with helium. The total flow rate of feed is 320 ml/min was mixed from gas 1, gas 2 and gas 3 are shown in the Table 11. Sulfur dioxide (SO₂) and hydrogen sulfide (H₂S), was analyzed by a gas chromatograph (GC-2014) containing Porapak QS column. Methane (CH₄) and carbon dioxide (CO₂) were analyzed by a gas chromatograph (GC-8A) containing Porapak Q column. A flow diagram of reaction system are shown in Figure 5. Operating condition of gas chromatography are shown in Table 12. The conversion of H₂S were calculated by following equation:

$$x\% \text{ H}_2\text{S} = (\text{H}_2\text{S reacted} / \text{H}_2\text{S fed}) \times 100 \quad \text{----- (14)}$$

Table 11 Gas materials used in the reaction test.

Gas NO.	Gas materials	Supplier
Gas 1	Methane 48.8%, Carbon dioxide 48.2%, Nitrogen 1.5%, and Hydrogen sulfide 1.5%	Linde
Gas 2	1% Oxygen in Nitrogen	Linde
Gas 3	Helium Ultra High Purity (Purity 99.999%)	BIG

3.3 Catalyst characterization

3.2.1 X-ray diffraction (XRD)

The X-ray diffraction (XRD) patterns were investigated by a SIEMENS D5000 X-ray diffractometer with radiation of CuK α in scanning rate of 0.5 sec/step ($2\theta = 20^\circ$ to 80°). The crystallite size was calculated using the Scherrer's equation and α -alumina as the external standard.

3.2.2 Raman spectroscopy

Raman spectra used to analyzed the functional group of catalysts. The spectra were obtained on a spectrometer (DILORXY) with a CCD detector (liquid nitrogen cooled) with an Ar⁺ laser, emission line at 514.5 nm. Analyze in Raman shift of 100-1300 cm⁻¹ are accurate within 2 cm⁻¹. The power incident beam was 3 mW. The analyzed spot was 1 μm.

3.2.3 N₂-physisorption

The BET surface area (m²/g), average pore size diameters (nm), and pore volume (cm³/g) of catalyst were investigated by using N₂ physisorption technique on a Micromeritics ASAP 2020 automated system.

3.2.4 Inductively coupled plasma-optical emission spectrometry (ICP-OES)

The actual percentages of V₂O₅ loading of the catalysts were measured by inductively coupled plasma-optical emission spectrometry (ICP-OES), using an Iris advantage Thermo Jarrel Ash device. The principle of ICP is the instrument to analyze the number of elements in samples that were completely degraded to solution. Preparation of sample analysis by 0.01 g of catalyst was dissolve in 5 ml of sulfuric acid (98%) and then dilute with 100 ml of deionized water.

3.2.5 Scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX)

The morphology of catalysts and elemental distribution on the surface of catalysts were analyzed by Scanning Electron Microscopy with Energy Dispersive X-Ray Analysis (SEM-EDX) using Link Isis series 300 program SEM (JEOL model JSM-5800LV).

3.2.6 Fourier transform infrared spectroscopy (FT-IR)

The functional group of catalysts were analyzed by the Fourier transform infrared spectroscopy (FT-IR) that can analyze in the range of 400-4000 cm^{-1} . The resolution was 4 and a number of scan was 200.

3.2.7 Oxygen-Temperature programmed desorption (O_2 -TPD)

Temperature programmed desorption of oxygen (O_2 -TPD) technique was used to analyze the amount of oxygen (O_2) in the catalyst. 0.1 g of catalyst was packed in quartz reactor supported by quartz wool. In order to removal moisture in the catalyst, the catalyst was pre-heated with helium at 350 $^{\circ}\text{C}$ for 1 h and then cooled down to the room temperature. After that, 50 ml/min of the of 1% of O_2 in He was fed into the reactor for 1 h at room temperature. Then, purge the residual oxygen by He for 1.5 h. Finally, Temperature programmed desorption of oxygen was increased from room temperature to 800 $^{\circ}\text{C}$ (ramp rate of 10 $^{\circ}\text{C}/\text{min}$) The effluent of oxygen concentration was continuously recorded by using a thermal conductivity detector.

3.2.8 X-ray photoelectron spectroscopy (XPS)

The surface properties such as electronic state, chemical state, and atomic elemental concentrations were determined by the XPS on a Kratos Amicus X-ray photoelectron spectrometer with Mg $\text{K}\alpha$ X-ray source. The internal standard of XPS spectra of C 1s line at binding energy was 285.0 eV.

CHAPTER IV

RESULTS AND DISCUSSION

The characteristics and catalytic activity of V_2O_5 dispersed on pure CeO_2 and CeO_2 - MO_2 mixed oxide supports prepared with different molar ratios between CeO_2 and MO_2 in the selective oxidation of H_2S to sulfur element were reported and discussed in this chapter. The properties and characteristics of catalysts were analyzed by X-ray diffraction (XRD), Raman spectroscopy, N_2 -physisorption, inductively coupled plasma-optical emission spectrometry (ICP-OES), scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX), Fourier transformed Infrared spectroscopy (FT-IR), X-ray photoelectron spectroscopy (XPS), and oxygen-temperature programmed desorption (O_2 -TPD. In the last part, the catalytic performed in H_2S oxidation at $130^\circ C$ and atmospheric pressure were discussed.

4.1 X-ray diffraction (XRD)

The X-ray diffraction (Figure 6) was used to investigate the structure of V_2O_5 supported on different supports. The X-ray diffraction peak corresponding to cerium oxide were evidenced at 2 theta $\sim 28.6^\circ$, 33.1° , 47.5° , and 56.3° [31, 32]. The peaks at 2 theta $\sim 28.6^\circ$, 33.2° , 47.5° , and 56.3° suggesting CeO_2 were observed for all catalysts, whereas the diffraction peaks corresponding to V_2O_5 were not detected, suggesting that they were highly dispersed on the support at low 3 wt.% loading. According to the literature [33], the XRD peak of V_2O_5 supported on ceria appeared when V_2O_5 was increased to more than 20 wt.%. The X-ray diffraction peaks of cerium vanadate which could be obtained from the reaction between CeO_2 and V_2O_5 due to high calcination temperature ($> 500^\circ C$) and high V_2O_5 loading ($> 20\%$ wt.%) according to the following reaction were also not detected [11]:

For the case of mixed oxide support catalysts (Figure 7-8), no diffraction peak of SiO_2 were detected as it is known to be an amorphous [30]. In case of $\text{V}_2\text{O}_5/\text{CeO}_2\text{-TiO}_2$, a diffraction patterns of the ceria along with low intensity TiO_2 anatase phase peak were observed. The anatase phase TiO_2 with high crystallinity can be observed at 2 theta $\sim 25^\circ$, 37° , and 53° [34]. Preuss et al. [35] reported Ce-Ti-O oxides specifically Ce_2TiO_5 , $\text{Ce}_2\text{Ti}_2\text{O}_7$ and $\text{Ce}_4\text{Ti}_9\text{O}_{24}$ by heating the mixtures of solida containing Ce and Ti at high temperature of 1250°C . However, the crystalline phase as mentioned could not be observed in the present study due to lower calcination temperature of 500°C . Lin et al. [36] suggested the Ti^{4+} enter the CeO_2 lattice at the interface to form octahedral site because titanium is locked by 8 coordinated oxygen atoms as surrounding cerium [36, 37]. For $\text{V}_2\text{O}_5/\text{CeO}_2\text{-ZrO}_2$, in addition to the CeO_2 X-ray diffraction peaks, the X-ray diffraction of another cubic fluorite-type in composition of $\text{Ce}_{0.4}\text{Zr}_{0.6}\text{O}_2$ was detected at 2 theta $\sim 29.8^\circ$, 34.8° , 49.6° and 58.3° [38].

Figure 6 X-ray diffraction patterns of $\text{V}_2\text{O}_5/\text{CeO}_2\text{-14}$ (VC14), $\text{V}_2\text{O}_5/\text{CeO}_2\text{-8}$ (VC8), $\text{V}_2\text{O}_5/\text{CeO}_2\text{-TiO}_2$ (VCT), $\text{V}_2\text{O}_5/\text{CeO}_2\text{-SiO}_2$ (VCS) and $\text{V}_2\text{O}_5/\text{CeO}_2\text{-ZrO}_2$ (VCZ) catalyst: (*) line due to CeO_2 ; (Δ) line due to TiO_2 anatase; (o) line due to $\text{Ce}_{0.4}\text{Zr}_{0.6}\text{O}_2$.

4.2 Raman spectroscopy

High specific surface area V_2O_5/CeO_2-SiO_2 and low specific surface area V_2O_5/CeO_2-TiO_2 catalysts were selected for the investigation of the dispersion of V_2O_5 on the support in comparison to the V_2O_5/CeO_2-8 by Raman spectroscopy technique. Figure 9 showed raman spectra of ceria at 462 cm^{-1} . No peaks corresponding to the crystalline of V_2O_5 were observed for all the samples (Raman spectra at $995, 702, 527, 404$ and 284 cm^{-1}), in agreement with the results from XRD that all the catalysts exhibited good dispersion of the vanadium species on the supports. [29, 39]

Figure 9 Raman spectroscopy of V_2O_5/CeO_2-8 (VC8), V_2O_5/CeO_2-TiO_2 (VCT) and V_2O_5/CeO_2-SiO_2 (VCS) catalyst.

4.3 N₂-physisorption

The BET surface area (m²/g), pore volume (cm³/g), and average pore diameter (nm) of the catalysts are given in the Table 13. Clogging of the catalyst pores from V₂O₅ species resulted in low distribution on the surface. V₂O₅/CeO₂-SiO₂ had the highest specific surface (144.5 m²/g) and was higher than pure supported ceria V₂O₅/CeO₂-8 and V₂O₅/CeO₂-14 (56.7 and 49.1 m²/g, respectively). The high specific surface area of V₂O₅/CeO₂-SiO₂ corresponded to the highest amount of pore volume (0.28 cm³/g). On the other hand, V₂O₅/CeO₂-TiO₂ had lowest specific surface area and the lowest amount of pore volume (0.04 cm³/g). The average crystal size of CeO₂ was calculated from the FWHM (full width at half maximum) of XRD peak corresponding to crystalline of CeO₂ at 2 theta ~ 28.6° in Figure 6-8 using the Scherrer's equation. Smaller crystallite size of CeO₂ in the range of 3-6 nm was found on all the mixed-oxide supported catalysts. The crystallite size decreased in the following order: V₂O₅/CeO₂-14 (14 nm) > V₂O₅/CeO₂-8 (8 nm) > V₂O₅/CeO₂-SiO₂ (5 nm) > V₂O₅/CeO₂-TiO₂ = V₂O₅/CeO₂-TiO₂ (3 nm).

Table 13 Vanadium composition (wt.%) and physical properties of 3 wt.% V₂O₅/CeO₂-MO₂ catalyst

Catalyst	N ₂ Physisorption			Crystallize size of CeO ₂ (nm) ^a
	SA (m ² /g)	Pore volume (cm ³ /g)	Average pore diameter (nm)	
3%V ₂ O ₅ /CeO ₂ -8 (VC8)	56.7	0.18	11.9	8
3%V ₂ O ₅ /CeO ₂ -14 (VC14)	49.1	0.10	7.6	14
3%V ₂ O ₅ /CeO ₂ -TiO ₂ (VCT)	27.0	0.04	6.0	3
3%V ₂ O ₅ /CeO ₂ -SiO ₂ (VCS)	144.5	0.28	7.8	5
3%V ₂ O ₅ /CeO ₂ -ZrO ₂ (VCZ)	69.8	0.09	4.7	3

^a Crystallite size was calculated from the Scherrer's equation

From the above characterization results from N₂ physisorption and XRD, small crystallite size of CeO₂ and high specific surface area were obtained after SiO₂ was doped to the V₂O₅/CeO₂ with molar ratio 1:1 based on mixed-oxide support so, the ratio of CeO₂-SiO₂ was further varied in different ratios at 1:2, 1:3, 2:1 and 3:1 to investigate the physical properties and performances of CeO₂-SiO₂ supported catalysts. From Table 14, it was found that increasing SiO₂ molar ratio resulted in the increased specific surface area, and vice versa for increasing CeO₂ molar ratio. In the case of V₂O₅/CeO₂-TiO₂ with molar ratio 1:1, 1:2 and 2:1, the specific surface area were not much changed between 19.8-21.4 m²/g and were found to be less than the pure supported ceria (V₂O₅/CeO₂-8 and V₂O₅/CeO₂-14). The crystallite size of CeO₂ on all the mixed-oxide supported catalyst were also in the range of 3-6 nm.

4.4 Inductively coupled plasma-optical emission spectrometry (ICP-OES) and Scanning electron microscopy with energy dispersive X-ray spectroscopy (SEM-EDX)

The actual metal loading amounts on the mixed metal oxide supports as determined by the ICP-OES shown in Table 15 were close to the design amount at 3 wt.% V_2O_5 loading amount. The analysis results from EDX showed the composition of element, V_2O_5/CeO_2-SiO_2 had the highest vanadium distribution on the surface of support compared to the other catalyst .

4.5 Fourier transforms infrared spectroscopy (FT-IR)

The Fourier transforms infrared spectroscopy (FTIR) spectra of the catalysts are shown in Figure 10-12. The Ce-O stretching mode was seen between at $500-700\text{ cm}^{-1}$ [40]. According to the spectra, the presence of CeO_2 particles were confirmed [40, 41]. The bands were attributed to the bending vibration of adsorbed water appearing at around 1660 cm^{-1} . For the -OH groups, the broad bands are shown at $3200-3600\text{ cm}^{-1}$ [6, 42]. To confirm the formation of V_2O_5 , overtone of V=O absorption bands mod was assigned at $1900-2100\text{ cm}^{-1}$ [39]. The band at 1083 cm^{-1} which was clearly observed, was attributed to the Si-O-Si stretching [8]. In case of VCT, the peak was seen around between at $600-800\text{ cm}^{-1}$ related to the O-Ti-O bonding in TiO_2 anatase phase [43, 44]. The attributed to the vibration of ZrO_3^{2-} , the region between at $497-502\text{ cm}^{-1}$ were observed [45, 46].

4.6 Oxygen-Temperature programmed desorption (O₂-TPD)

The oxygen-temperature programmed desorption (O₂-TPD) analysis was carried out in order to investigate the ability to adsorb and desorb molecules of oxygen on the catalyst surface, the analysis results are shown in Figure 15-17. The first peak at low temperature less than 300 °C represent to the physically adsorbed oxygen (O₂[·]) or weakly chemisorbed oxygen. The peak area consistent with the specific area of catalyst. The high peak area of V₂O₅/CeO₂-SiO₂ explained the high specific surface area of catalyst. The second desorption peak appeared at 300-700 °C corresponding to strongly chemically adsorbed oxygen (O₂²⁻/O⁻) on the oxygen vacancies. The desorption peak of chemically adsorbed oxygen was observed at lower temperature on V₂O₅/CeO₂-SiO₂ suggesting that the desorption of chemically adsorbed oxygen on the oxygen vacancies for V₂O₅/CeO₂-SiO₂ was easier than the others catalyst. It is indicated that the capability of adsorption, mobility and desorption of oxygen (O₂²⁻/O⁻) on oxygen vacancies was easier which resulted in the faster re-oxidation step of V⁴⁺ to V⁵⁺ than the others catalyst. In the case of V₂O₅/CeO₂-TiO₂, a sharp second peak around temperature of 200-700 °C corresponded to the chemically adsorbed oxygen on the oxygen vacancies but the peak shifted to high temperature so, the re-oxidation step of reaction must be slower than V₂O₅/CeO₂-SiO₂. Henrik Høgh et al. [47] also suggested that the largest peak of chemically adsorbed oxygen on the oxygen vacancies on V₂O₅/CeO₂-TiO₂ due to the oxygen vacancies on the support titania. The unpaired of electron occur when oxygen atom of titania was removed to form oxygen vacancies while V₂O₅/TiO₂ synthesized, reduce Ti⁴⁺ to Ti³⁺. The electron will react to the V₂O₅ to form VO³⁺ and VO²⁺. The desorption peaks, which were observed at higher temperature (700-800 °C) due to desorption of lattice oxygen (O²⁻). Obviously, the oxygen vacancy promote the O₂ dissociative adsorption to formation the oxygen ion (O²⁻) which could re-oxidize the partially active phase of V₂O_{5-x} component [31, 48, 49].

Figure 13 O_2 -TPD profile of V_2O_5/CeO_2 -14 (VC14), V_2O_5/CeO_2 -8 (VC8), V_2O_5/CeO_2-TiO_2 (VCT), V_2O_5/CeO_2-SiO_2 (VCS) and V_2O_5/CeO_2-ZrO_2 (VCZ) catalyst:

Figure 15 O_2 -TPD profile of V_2O_5/CeO_2-SiO_2 (VCS) with vary molar ratio base oxide ($CeO_2:SiO_2$)

4.7 X-ray photoelectron spectroscopy (XPS)

The chemical state of Ce 3d and O 1s and surface composition were investigated by using XPS technique. The XPS spectra of Ce 3d of catalysts are shown in Figure 16, the peaks labeled p and q are related to spin-orbital state of $3d_{2/5}$ and $3d_{2/3}$, respectively. Additionally, the labeled p1 and q1 correspond to Ce^{3+} whereas the peaks labeled p, p2, p3, q, q2 and q3 represent to Ce^{4+} . The partial existence of Ce^{3+} was determined by XPS analysis. The area percentage of Ce^{3+} is determined to be VC8 (40%) > VC14 \approx VCT \approx VCS \approx VCZ (19-22%) > VCS12 (12%). As is known Ce^{3+} can result in a charge imbalance, oxygen vacancies occur on the surface of catalyst are favorable for the formation of chemically adsorbed oxygen on the oxygen vacancies, which has been reported to be the most active oxygen directly affect to performance of catalyst in the oxidation reaction [32].

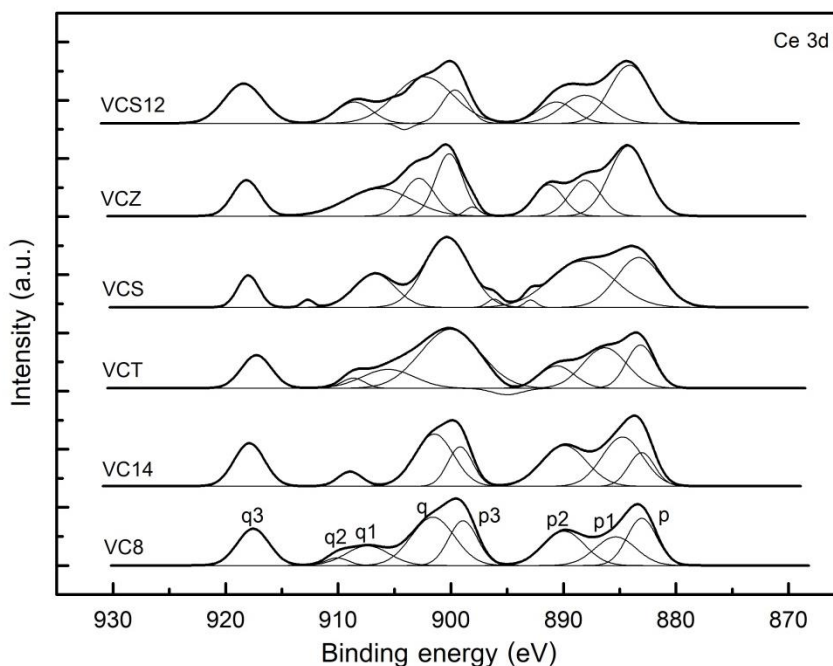

Figure 16 XPS Ce 3d spectra of V_2O_5/CeO_2 -14 (VC14), V_2O_5/CeO_2 -8 (VC8), V_2O_5/CeO_2 - TiO_2 (VCT), V_2O_5/CeO_2 - SiO_2 (VCS), V_2O_5/CeO_2 - ZrO_2 (VCZ) and V_2O_5/CeO_2 - SiO_2 1:2 (VCS12) catalyst.

The XPS spectra of O 1s were deconvoluted into 3 peaks representing 3 types of oxygen species as shown in Figure 17. The binding energy values of O 1s reported around 530 eV was attributed to the lattice oxygen species (O_l) of V_2O_5 and CeO_2 while the binding energy values of O 1s reported around 531.5 eV was represented to the surface oxygen (O_s) although the binding energy values of O 1s reported around 533 eV was accordance with the adsorbed molecular water (O_w). The surface oxygen related to the chemically adsorbed oxygen on the oxygen vacancies, which has been reported to be the most active oxygen directly affect to performance of catalyst in the oxidation reaction. From Table 4.4, the ratios of $O_s/(O_l+O_s)$ were found to be in the following order: VCT > VCZ > VC8 > VC14. Liu et al. [50] suggested the O 1s peak around 533 eV of V_2O_5/CeO_2 - SiO_2 correspond to oxygen in SiO_2 , ensure the ability to adsorb water of silica

encourage to larger peak of adsorbed molecular water (O_w) observed and complicate the other peaks.

Figure 17 XPS O 1s spectra of V_2O_5/CeO_2 -14 (VC14), V_2O_5/CeO_2 -8 (VC8), V_2O_5/CeO_2 - TiO_2 (VCT), V_2O_5/CeO_2 - SiO_2 (VCS), V_2O_5/CeO_2 - ZrO_2 (VCZ) and V_2O_5/CeO_2 - SiO_2 1:2 (VCS12) catalyst.

The XPS spectra of V 2p were fitted and deconvoluted into 2 peaks indicating of V^{5+} and V^{4+} species in form of V_2O_5 and V_2O_4 , respectively (Figure 18). According to the literature, the binding energy of vanadium ions in form of vanadium oxide for instance V_2O_5 , V_2O_4 and V_2O_3 reported around 517.2-517.7 eV, 516.2-516.6 and 515.2-515.9 eV. Nevertheless, the binding energy of V 2p in this study were slightly shifted higher due to decreasing of electron around V atom as Chi et al. [20] reported, due probably to the intimate contact of the two metal oxides (active site and support) caused the decrease in electron density of V and Ce resulting in higher binding energy of V 2p on the V_2O_5/CeO_2 catalyst. However, the partial existence of V^{4+} was determined by XPS

analysis, and the area percentage of $V^{4+}/(V^{4+}+V^{5+})$ is found to be $VC8 > VC14$. For the other catalysts, the chemical state of V species could not be detected by XPS. The lower valence state of vanadium ion may be formed, which related to interaction between vanadium oxide and support [21]. Therefore, V^{4+} could be more oxygen vacancies for improving the electron transfer result to strong redox capability.

Figure 18 XPS V 2p spectra of V_2O_5/CeO_2 -14 (VC14), V_2O_5/CeO_2 -8 (VC8), V_2O_5/CeO_2 - TiO_2 (VCT), V_2O_5/CeO_2 - SiO_2 (VCS), V_2O_5/CeO_2 - ZrO_2 (VCZ) and V_2O_5/CeO_2 - SiO_2 1:2 (VCS12) catalyst.

4.8 Catalytic test in the selective oxidation of H₂S to sulfur

The catalytic tests in the selective oxidation of H₂S to elemental sulfur were conducted in order to investigate the performances of the prepared V₂O₅ on different mixed metal oxides at temperature of 130 °C. By plotting the conversion-time profiles in Figure 18, it can be seen that the V₂O₅/CeO₂-SiO₂ with the highest specific surface area of 149 m²/g exhibited the highest conversion of H₂S at ~73% during the 3 h reaction time. The V₂O₅/CeO₂-8, V₂O₅/CeO₂-TiO₂, V₂O₅/CeO₂-14 and V₂O₅/CeO₂-ZrO₂ exhibited 66%, 64%, 61% and 57% H₂S conversion, respectively.

The nature of support plays an important role in determination the properties of catalyst, the supported vanadium interaction affects redox properties and dispersion of active site on the support. Previous report showed that CeO₂ has the ability to capture, store and transfer surface oxygen species which exhibits exceptional redox properties so, presumable supplies active oxygen to V₂O₅ that are reduced during the reaction [34, 51]. In the present study, different metal oxides (TiO₂, SiO₂ and ZrO₂) were doped to modify the catalysts. The smaller CeO₂ crystallite size suggested the subsistence of a strong interaction between CeO₂ support and mixed-oxide support resulting in the improved performances of catalyst. The highest H₂S conversion on the V₂O₅/CeO₂-SiO₂ catalysts was correlated to the highest specific surface area, the smallest CeO₂ crystallite size, and the lowest desorption temperature for adsorption-desorption temperature of oxygen. In the same trend, Kugai et al. [52] reported the smaller crystallite size of ceria after Rh were doped result to highest ethanol conversion in oxidation of ethanol reaction. Kundakovic et al. [53] reported the smaller crystallite size of ceria accommodated the formation of highly reducible O₂ and increase activity of methane oxidation. The effect of crystallite size to the activity of catalyst can observed from the experiments using pure CeO₂, the results showed higher H₂S conversion on V₂O₅/CeO₂-8 (crystallite size = 8 nm) than on V₂O₅/CeO₂-14 (crystallite size = 14 nm).

Considering the V_2O_5/CeO_2-TiO_2 and V_2O_5/CeO_2-ZrO_2 , the conversion of H_2S were lower than V_2O_5/CeO_2-SiO_2 although the crystallite sizes of CeO_2 were quite similar but the specific surface area of the V_2O_5/CeO_2-TiO_2 and the V_2O_5/CeO_2-ZrO_2 were less than the V_2O_5/CeO_2-SiO_2 . The catalysts also desorb oxygen on oxygen vacancies at higher temperature. Thus, the re-oxidation which is the limiting step for the selective oxidation of H_2S to sulfur element was slower comparing to the V_2O_5/CeO_2-SiO_2 catalyst.

Due to the complex of the H_2S oxidation reaction, SO_2 was also formed by a secondary reaction of sulfur on the catalyst surface [8]. Plotting concentration of SO_2 time profiles showed the SO_2 concentration less than 20 ppm with no change of CO_2 and CH_4 for all the V_2O_5/CeO_2 and V_2O_5/CeO_2-MO_2 catalysts. To confirm the presence of sulfur element product, used catalysts were characterized by EDX and the highest amount of sulfur element was found to deposit on the V_2O_5/CeO_2-SiO_2 at 5.5 wt.% (H_2S conversion $\sim 73\%$). For the V_2O_5/CeO_2-8 (H_2S conversion $\sim 66\%$) and V_2O_5/CeO_2-8 (H_2S conversion $\sim 61\%$) the elemental sulfur deposited on the catalyst were 4.1 wt.% and 3.9 wt.%, respectively.

Figure 19 (a) H₂S conversion (b) SO₂ concentration as a function of time of supported V₂O₅ catalyst.

The best catalyst from the first part of the study was selected to study the effect of mixing molar ratios between CeO₂ and MO₂ support on the catalytic performance for selective catalytic oxidation of H₂S. V₂O₅/CeO₂-TiO₂ and V₂O₅/CeO₂-SiO₂ were selected to further study. The molar ratio between CeO₂ and MO₂ were varied in order: 1:2, 1:3, 2:1 and 3:1. For the case of V₂O₅/CeO₂-TiO₂, the optimum molar ratio of VCT was 1:1 in which the catalyst was mostly active among the VCT catalyst series. Higher component of TiO₂ occur two electrons will leave the polarons and will react with the V₂O₅ cluster to form and VO₃⁻ and VO₂⁻ result to low activity [47]. From Figure 21, the experiment results showed that V₂O₅/CeO₂-SiO₂ with 1:1 molar ratio base metal oxide exhibited the highest conversion of H₂S among the VCS catalyst series. According to Shin et al. [47], a characteristic of reduced V₂O₅, such as V₂O₃ and V₂O₄ which were found on V₂O₅/SiO₂ affected the re-oxidation to its original V₂O₅ with difficulty. Therefore, higher component of SiO₂ in support disguised good properties of ceria resulting in poor performances of catalyst. Decreasing of H₂S conversion of VCS21 and VCS31 compared with VCS due to the decreasing component of SiO₂ led to low specific surface area.

Plotting concentration of SO_2 time profiles showed the SO_2 concentration less than 20 ppm with no change of CO_2 and CH_4 for all the $\text{V}_2\text{O}_5/\text{CeO}_2$ and $\text{V}_2\text{O}_5/\text{CeO}_2\text{-MO}_2$ catalysts similar to the previous part.

CHAPTER V

CONCLUSIONS AND RECCOMENDATIONS

5.1 Conclusion

The characteristics and catalytic activity of V_2O_5 dispersed on pure CeO_2 and CeO_2 - MO_2 mixed oxide supports prepared with different molar ratios between CeO_2 and MO_2 in the selective oxidation of H_2S were reported and discussed. The catalytic activity tests were carried out in H_2S oxidation at $130\text{ }^\circ\text{C}$ and atmospheric pressure. The characteristics of catalysts were analyzed by XRD, N_2 physisorption, ICP-OES, SEM-EDX, FTIR, and O_2 -TPD. Ceria has the ability to capture, store and transfer surface oxygen species which exhibits exceptional redox properties so, presumably supplies active oxygen to V_2O_5 that are reduced during the reaction. It is suggested that interaction between V_2O_5 and support and well dispersion of active site played an importance role in determining the performance of catalysts. From this study, the effect of adding mixed-metal oxide support led to smaller CeO_2 crystallite suggesting the subsistence of a strong interaction between CeO_2 support and the mixed-oxide support. V_2O_5/CeO_2 - SiO_2 catalysts exhibited the highest specific surface area, smallest crystallite size, and lowest desorption temperature for adsorption-desorption temperature of oxygen on the oxygen vacancies, indicating the easier desorption of chemically adsorbed oxygen (O_2^{2-}/O) on the oxygen vacancies for V_2O_5/CeO_2 - SiO_2 as compared to the others catalyst. The highest partial existence of Ce^{3+} on V_2O_5/CeO_2 - SiO_2 catalyst also favored the formation of chemically adsorbed oxygen on the oxygen vacancies, which could be the most active oxygen directly affecting the performance of catalyst in the oxidation reaction. In addition, the presence of partially reduced V-Ce may influence the amount of active surface oxygen (O_s) which led to the easier adsorb/desorb oxygen on the oxygen vacancies. V^{4+} with more oxygen vacancies can develop strong redox capability and improved catalytic performance as shown by the higher activity of VC8 comparing to VC14. The products from this reaction are sulfur element and $SO_2 < 20$ ppm with no change of CO_2 and CH_4 . It may be applied in H_2S removal from biogas.

5.2 Recommendations

1. The effect of amount dopant on the characteristics and properties of V_2O_5 on supports should be further studied in the selective oxidation of H_2S .
2. The characterization of V_2O_5 catalysts supported on the supports should be analyzed by high resolution analytical techniques because of very low content of dopant.
3. The characterization of mixed-oxide supported catalysts with vary molar ratio should be analyzed by more technique in order to explain and discuss.
4. The stability and catalyst deactivation of catalysts should be further tested.

APPENDIX A

CALCULATION FOR CATALYST PREPARATION

A1. Calculation for the CeO₂-TiO₂ support preparation (1:1 molar ratio base on oxide)

Chemical information

Cerium (III) nitrate hexahydrate, 99.5% $M_w = 434.22$ g/mol

Titanium (IV) butoxide, 97% $M_w = 340.32$ g/mol

Calculation

To preparation 1:1 molar ratio base on oxide of CeO₂-TiO₂ support following:

- Desire CeO₂ 0.0086 mole

- Desire TiO₂ 0.0086 mole

Prepare Ce(NO₃)₃·6H₂O for CeO₂ 0.0086 mole

$$0.0086 \text{ mole CeO}_2 \times \frac{1 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}}{0.995 \text{ mole Ce}} \times \frac{1 \text{ mole Ce}}{1 \text{ mole CeO}_2} = 0.00864 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}$$

$$0.00864 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O} \times \frac{434.22 \text{ g Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}}{1 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}} = 3.75 \text{ g Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}$$

Prepare Ti(C₄H₉O)₄ for TiO₂ 0.0086 mole

$$0.0086 \text{ mole TiO}_2 \times \frac{1 \text{ mole Ti(C}_4\text{H}_9\text{O)}_4}{0.97 \text{ mole TiO}_2} = 0.0089 \text{ mole Ti(C}_4\text{H}_9\text{O)}_4$$

$$0.0089 \text{ mole Ti(C}_4\text{H}_9\text{O)}_4 \times \frac{340.32 \text{ g Ti(C}_4\text{H}_9\text{O)}_4}{1 \text{ mole Ti(C}_4\text{H}_9\text{O)}_4} = 3.02 \text{ g Ti(C}_4\text{H}_9\text{O)}_4$$

So, for preparation of CeO₂-TiO₂ support, used 3.75 g Ce(NO₃)₃·6H₂O and 3.02 g Ti(C₄H₉O)₄

A2. Calculation for the CeO₂-SiO₂ support preparation (1:1 molar ratio base on oxide)

Chemical information

Ammonium cerium (IV) nitrate: Ce(NH₄)₂(NO₃)₆, 99.99% M_w = 548.22 g/mol

Colloidal silica 40% in water, ρ = 1.3 g/ml M_w = 60.08 g/mol

Calculation

To preparation 1:1 molar ratio base on oxide of CeO₂-SiO₂ support following:

- Desire CeO₂ 0.0086 mole

- Desire SiO₂ 0.0086 mole

Prepare Ce(NH₄)₂(NO₃)₆ for CeO₂ 0.0086 mole

$$0.0086 \text{ mole CeO}_2 \times \frac{1 \text{ mole Ce(NH}_4)_2(\text{NO}_3)_6}{0.9999 \text{ mole Ce}} \times \frac{1 \text{ mole Ce}}{1 \text{ mole CeO}_2} = 0.0086 \text{ mole Ce(NH}_4)_2(\text{NO}_3)_6$$

$$0.0086 \text{ mole Ce(NH}_4)_2(\text{NO}_3)_6 \times \frac{548.22 \text{ g Ce(NH}_4)_2(\text{NO}_3)_6}{1 \text{ mole Ce(NH}_4)_2(\text{NO}_3)_6} = 4.71 \text{ g Ce(NH}_4)_2(\text{NO}_3)_6$$

Prepare colloidal silica for SiO₂ 0.0086 mole

$$0.0086 \text{ mole SiO}_2 \times \frac{1 \text{ mole colloidal silica}}{0.4 \text{ mole SiO}_2} = 0.0215 \text{ mole colloidal silica}$$

$$0.0215 \text{ mole colloidal silica} \times \frac{60.08 \text{ g colloidal silica}}{1 \text{ mole colloidal silica}} \times \frac{\text{ml}}{1.3 \text{ g}} = 0.99 \text{ ml colloidal silica}$$

So, for preparation of CeO₂-SiO₂ support, used 4.71 g Ce(NH₄)₂(NO₃)₆ and 0.99 ml colloidal silica

A3. Calculation for the CeO₂-ZrO₂ support preparation (1:1 molar ratio base on oxide)

Chemical information

Cerium (III) nitrate hexahydrate, 99.5% $M_w = 434.22$ g/mol

Zirconium (IV) oxynitrate hydrate, 99% $M_w = 231.23$ g/mol

Calculation

To preparation 1:1 molar ratio base on oxide of CeO₂-ZrO₂ support following:

- Desire CeO₂ 0.0086 mole

- Desire ZrO₂ 0.0086 mole

Prepare Ce(NO₃)₃·6H₂O for CeO₂ 0.0086 mole

$$0.0086 \text{ mole CeO}_2 \times \frac{1 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}}{0.995 \text{ mole Ce}} \times \frac{1 \text{ mole Ce}}{1 \text{ mole CeO}_2} = 0.00864 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}$$

$$0.00864 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O} \times \frac{434.22 \text{ g Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}}{1 \text{ mole Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}} = 3.75 \text{ g Ce(NO}_3)_3 \cdot 6\text{H}_2\text{O}$$

Prepare ZrO(NO₃)₂·2H₂O for ZrO₂ 0.0086 mole

$$0.0086 \text{ mole ZrO}_2 \times \frac{1 \text{ mole ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O}}{0.99 \text{ mole ZrO}_2} = 0.0087 \text{ mole ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O}$$

$$0.0087 \text{ mole ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O} \times \frac{231.23 \text{ g ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O}}{1 \text{ mole ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O}} = 2.01 \text{ g ZrO(NO}_3)_2 \cdot 2\text{H}_2\text{O}$$

So, for preparation of CeO₂-ZrO₂ support, used 3.75 g Ce(NO₃)₃·6H₂O and 2.01 g

ZrO(NO₃)₂·2H₂O

A4. Calculation for the 3 wt.% V₂O₅/CeO₂ catalyst preparation

Chemical information

Ammonium metavanadate, 99.99%	M _w = 116.98 g/mol
Vanadium pentoxide	M _w = 181.88 g/mol
Cerium (IV) oxide	M _w = 172.115 g/mol

Calculation

To preparation 3 wt.% V₂O₅/CeO₂ catalyst follow:

- Desire CeO₂ 2 g
- Desire V₂O₅ 3 wt.%

For 3 wt.% V₂O₅/CeO₂ 100 g

Consist of CeO₂ 97 g V₂O₅ 3 g

$$\text{If } \text{CeO}_2 \text{ 2 g } \quad \text{V}_2\text{O}_5 = 2 \text{ g CeO}_2 \times \frac{3 \text{ g V}_2\text{O}_5}{97 \text{ g CeO}_2} = 0.062 \text{ g V}_2\text{O}_5$$

Prepare NH₄VO₃ for V₂O₅ 0.062 g

$$0.062 \text{ g V}_2\text{O}_5 \times \frac{1 \text{ mole V}_2\text{O}_5}{181.88 \text{ g V}_2\text{O}_5} = 0.00341 \text{ mole V}_2\text{O}_5$$

$$0.00341 \text{ mole V}_2\text{O}_5 \times \frac{2 \text{ mole NH}_4\text{VO}_3}{1 \text{ mole V}_2\text{O}_5} = 0.00682 \text{ mole NH}_4\text{VO}_3$$

$$0.00682 \text{ mole NH}_4\text{VO}_3 \times \frac{116.98 \text{ g NH}_4\text{VO}_3}{1 \text{ mole NH}_4\text{VO}_3} \times \frac{1}{0.9999} = 0.80 \text{ g NH}_4\text{VO}_3$$

So, for preparation of 3 wt.% V₂O₅/CeO₂ catalyst, used 2 g CeO₂ and 0.80 g NH₄VO₃

APPENDIX B

CALCULATION OF THE CRYSTALLITE SIZE

B1. Calculation of the crystallite size of CeO₂ by using Debye – Scherrer's equation

The average crystal size of CeO₂ used Scherrer's equation to calculate from FWHM (full width at half maximum) of XRD peak corresponding crystalline of CeO₂ at 2 theta ~ 28.6° follow equation:

$$D = \frac{K\lambda}{\beta \cos\theta}$$

Where;

- D = Crystallite size, Å
- K = Crystallite-shape factor (= 0.9 for FWHM of spherical crystals with cubic symmetry)
- λ = the X-ray wavelength, 1.5418 Å for CuK α
- β = X-ray diffraction broadening, radian
- θ = Observes peak angel, degree

Example

Calculation of the crystallite size of CeO₂ (< 25 nm, supplier: Sigma Aldrich)

Information The major peak of CeO₂ was observed at 2 theta ~ 28.55°
The half-height width of the diffraction peak at 28.55° = 0.42°

Calculation

$$28.55^\circ \text{ to radian} = \frac{28.55(2\pi)}{360} = 0.5 \text{ radian}$$

$$0.42^\circ \text{ to radian} = \frac{0.42(2\pi)}{360} = 0.0073 \text{ radian}$$

$$\begin{aligned} D &= \frac{K\lambda}{\beta \cos\theta} \\ &= \frac{0.9(1.5418)}{0.0073 \cos 0.5} \\ &= 190.1 \text{ \AA} \\ &= 19 \text{ nm} \end{aligned}$$

APPENDIX C

CALIBRATION CURVE

The calibration curve is used to calculate a concentration of substance. It is created from area which analyzed by injecting the standard gas at different volumes into GC (gas chromatography). Plotting graph between peak area at different concentrations (x-axis) and mole or concentration of gas (y-axis).
